Some countries have already risen to the challenge. A recent best seller reports large-scale government-sponsored research in Soviet countries that has allegedly resulted in some startling psychic discoveries (4). One, with far-reaching political and paramilitary implications, deals with the possibility of influencing human behavior ("brainwashing") and even matter (psychokinesis) by telepathic remote control. Another—of special interest to space exploration—alludes to instant telepathic communication over immense distances via theoretical units of thought, called tachyons.

There have even been attempts to explain supernatural religious beliefs on a scientific basis. For example, a special high-frequency photographic technique, known after its Russian proponents as the "Kirlian effect" (5), has allegedly revealed luminous pulsating energy waves that are emitted into the atmosphere by all forms of life; these waves presumably intermingle and interact with other emanations, past, present, and future, and can theoretically be detected by properly developed human and mechanical sensors. Thelma Moss and her coworkers at the University of California, Los Angeles, have succeeded in taking similar photographs (6). The question naturally arises whether such emanations correspond to the religious conceptions of the soul and, in turn, lend credence to the claims of gifted psychics that they are

Read at a panel at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Dean is Clinical Professor of Psychiatry, University of Florida College of Medicine, Gainesville, and University of Miami Medical School, Fla. Address reprint requests to 2121 North Bayshore Drive, Miami, Fla. 33137.

able to "tune into" the emanations of other souls and cure sickness by the laying on of hands, to give two examples. If so, the human mind could be regarded as a super-sensitive receiver that is capable, in its highest development, of tuning into the innermost channels of the universe.

Such reports have excited interest and concern the world over. There is certainly an urgent need for the United States government to initiate similar research. It probably has considerable awareness of the problem already. The Army's intelligence agency, for instance, discussed the power of mental telepathy in a manual published by the Technical Bulletin Department of the Provost Marshal General's office entitled *Techniques of Surveillance and Undercover Investigation* (7).

DESCRIPTION OF THE ULTRACONSCIOUS

It seems strange that I should have become involved in psychic matters, for my orientation is decidedly pragmatic, and I have never experienced any ultraconscious manifestation stronger than an occasional flash of intuition, common to all of us. However, that may be all to the good, for it enables me to approach the subject with an unbiased attitude.

My interest was first aroused by a chance encounter with a Zen master in Tokyo, then by subsequent observation and filming of Zen Buddhist rituals during several visits to Japan (8) and also by interviews with several so-called "sensitives" or "psychics." I was impressed to find that great numbers of sensible, rational people in all walks of life, lay and professional, believed in the ultraconscious, had themselves experienced various manifestations of it, and had derived constructive benefit from it. We psychiatrists are conditioned to equate hallucinations with schizophrenia and other psychoses, but a great many nonpsychotic individuals also hear voices, see visions, and have other supernatural experiences. I am currently conducting intensive psychiatric evaluations on a series of such individuals in order to obtain a factual determination of their mental and emotional status.[1] As a physician I am particularly interested in any healing factors that clinical development of the ultraconscious may contribute to psychotherapy.

The ultraconscious summit, though rare, produces a superhuman transmutation that defies description. The mind, divinely intoxicated, literally reels and trips over itself, groping for words of sufficient exaltation to portray the experience. As yet, we have no such words. One cannot help but wonder if it is analogous to erotic love. Gopi Krishna believes that the ultraconscious (which he calls "Kundalini") is, in fact, a highly evolved transmutation of sex vitality (9).

To begin with, there are many *formes frustes* of the ultraconscious spectrum: they vary greatly in frequency, intensity, and duration in different persons and even in the same person at different times. They may occur at any time, awake or asleep, spontaneously or only after long years of arduous discipline.

From the welter of literature and liturgy, ancient and modern, I have summarized ten distinguishing characteristics of the ultraconscious summit:

1. The onset is ushered in by an awareness of light that floods the brain and fills the mind. In the East it is called the "Brahmic splendor." Walt Whitman speaks of it as ineffable light—"light rare, untellable, lighting the very light—beyond all signs, descriptions, languages" (10). Dante writes that it is capable of transhumanizing a man into a god and gives a moving description of it in lines of mystical incandescence from "Paradiso" of the *Divine Comedy* (11).
2. The individual is bathed in emotions of supercharged joy, rapture, triumph, grandeur, reverential awe, and wonder—an ecstasy so overwhelming that it seems little less than a sort of superpsychic orgasm.
3. A noetic illumination that is quite impossible to describe occurs. In an intuitive flash one has an awareness of the meaning and drift of the universe, an identification and merging with creation, infinity, and immortality, a depth beyond revealed meaning—in short, a conception of an "Over-Self," so omnipotent that religion has interpreted it as God.
4. There is a feeling of transcendental love and compassion for all living things.
5. Fear of death falls off like a mantle; physical and mental suffering vanish. There is an enhancement of mental and physical vigor and activity, a rejuvenation and prolongation of life. This property should command the special interest of psychiatry and medicine.
6. There is a reappraisal of the material things in life, an enhanced appreciation of beauty.
7. There is an extraordinary quickening of the intellect, an uncovering of latent genius and leadership.
8. There is a sense of mission. The revelation is so moving and profound that the individual is moved to share it with his fellowmen.
9. A charismatic change occurs in personality—an inner and outer radiance takes over, as if the person is charged with some divinely inspired power, a magnetic force that attracts and inspires others.
10. There is a sudden or gradual development of extraordinary perception, telepathy, precognition, or healing. Though generally regarded as occult, such phenomena may have a more rational explanation; they may be due to an awakening of the transhuman powers of perception latent in all of us.

DISCUSSION

The ultraconscious summit is a genuine metamorphosis of consciousness that has been experienced by certain sages, prophets, leaders, and men of genius through the ages. The factors producing it are as yet unknown, but the remarkable uniformity of distinguishing charac-

[1] This study is partially supported by a grant from the Academy of Parapsychology, Healing, and Psychic Sciences.

teristics should leave no doubt that a common denominator—empirically validated if not yet scientifically proven—underlies all of them. It is only a matter of time before science dissociates it from religious dogma and explains it to the satisfaction of the intellect in terms of naturalistic laws.

As ontogeny recapitulates phylogeny, so may the human mind be a microcosm that recapitulates the evolution of the universe, or so may "psychogeny recapitulate cosmogeny." This theory presupposes that the rudiments of the ultraconscious are present in all and can be prematurely awakened in some. If to do so would make a better world, then science will not long delay accepting the challenge.

Fortunately, there is no dearth of material. Though total ultraconsciousness is rare, a great variety of lesser manifestations exists in abundance. While the scientist studies them in his laboratory, the enlightened clinician can observe them in his practice. A simple first step would be to encourage people to disclose any paranormal ("supernatural") experiences and to treat such disclosures with an open-minded, noncynical attitude. The clinician will be amazed at the abundant material he can thus elicit. And if the resulting data from laboratory and clinic were collected, pooled, and analyzed, it could not help but result in rational breakthroughs.

Despite my lack of psychic powers, I can envision a tremendous upsurge in psychic research, with and without government support, in the near future. Is that clairvoyance or common sense? Perhaps the two are not so different after all.

How Success Nearly Wrecked a Residency Experience

BY FRANK M. KLINE, M.D.

The number of residents in a second-year program increased almost threefold between 1965 and 1971. Total patient visits increased by almost 100 percent. However, the average number of monthly patient visits per resident decreased, indicating a loss of efficiency. After discussing how the clinic dealt with this problem, the author concludes that increases of this magnitude require the addition of more supervising psychiatrists, changes in administrative style, and adequate clerical assistance and space.

THE SECOND-YEAR RESIDENCY PROGRAM at Los Angeles County-University of Southern California Medical Center expanded from nine residents in 1965 to 23 in 1971. During the same period, the total number of patient visits increased from 21,005 to 41,789. While this may look like success, it turned out that the average monthly number of patient visits per resident decreased. Two full-time supervising psychiatrists, additional office space, changes in administration, and other factors reversed this trend in 1970. Numbers may not be the only or the major indicator of "success," but they are one factor to consider (1, 2).

Dr. Kline is Associate Director, Adult Psychiatric Outpatient Clinic, Los Angeles County-University of Southern California Medical Center, 1237 North Mission Rd., Los Angeles, Calif. 90033, and Assistant Professor of Psychiatry, University of Southern California School of Medicine.

TABLE 1
Changes in Numbers of Residents and Patient Utilization (1965–1971)

Year	Number of Second-Year Residents	Total Patient Visits	Average Patient Visits per Month per Resident
1965	9	21,005	194.5
1966	12	25,275	175.5
1967	13	27,849	178.5
1968	17	27,475	134.7
1969	23	30,370	110.0
1970	21	36,474	114.7
1971	23	41,789	151.4

HISTORY

In 1959 the current director assumed his duties and found four second-year psychiatric residents and a few excellent volunteer supervisors. Over the years a new staff was developed with 30 highly qualified volunteer physician supervisors; five psychiatric social workers; three full-time, two half-time, and six quarter-time psychiatrists; a psychologist; a clinic nurse; a full-time pharmacist; and 23 residents. The clinic gained the community's respect and referrals from other services increased. The residency program gained in reputation because of the staff's wide clinical experience, the quality of supervision, and high salaries. The increase in the number of residents, the reputation of the clinic, and the successful efforts of the director to reduce the waiting time produced a gradually expanding patient load. A major crisis that was precipitated by insufficient office space occurred in 1968.

OBSERVATIONS

Table 1 shows the number of second-year residents for each year from 1965 to 1971—there was an increase from nine in 1965 to 23 in 1969—and in the yearly total patient visits for the same period. The total patient visits show an impressive increase from 21,005 in 1965 to 41,789 in 1971. The total number of patient visits includes patients seen by staff members, third-year residents, and other students. These account for 20 percent of the total. The number of residents more than doubled, while the total number of patient visits did not.

Table 1 also shows the average number of patient visits per month per resident. This figure does not represent the actual number of visits, but is obtained by dividing the total patient visits by the number of residents times 12. Since this does not take into account the 20 percent of patients seen by other staff members, the actual number of patient visits per month per resident would be about 20 percent lower than the figure shown in table 1.

The table shows that increasing the number of residents in training does not automatically increase either the total number of patient visits or the average number of patient visits per month per resident. Even additional staff may not help. For example, in 1968, the number of residents increased from 13 to 17. There was an additional full-time supervisor, but there was a decrease in total patient visits from 27,849 to 27,475. More surprising, the average patient visits fell from its 1965 level of 194.5 to 110 in 1969 as the number of residents increased from 9 to 23.

DISCUSSION

What happened was that the number of residents increased rapidly without a preceding change in administrative structure, the number of full-time staff and volunteer supervisors, adequate office space, auxiliary personnel, and number of patients.

By 1968, 17 residents and staff members were sharing space designed for two-thirds that number. Like Norwegian rats under crowded conditions, staff members were at each other's throats. Energy that should have gone to research training and patient care was dissipated in intra-office conflict (3). Residents and social workers argued over who was more important and, therefore, who was entitled to full-time versus half-time use of offices. The residents also complained to staff that "they were here to learn, not to treat." While this appeared to be an educational issue, it seemed related to the fact there was not enough office space in which to see patients and, therefore, the importance of clinical experience was denied. It also seemed that, for the residents to be helpful and caring toward patients, they had to feel cared for themselves.

Even the clinic director's six- by eight-foot office was shared with the clinic secretary, who left before the end of the year. Without secretarial help, our problems were compounded.

Other critical factors were an administrative structure designed for ten residents and an insufficient number of experienced paid and volunteer psychiatric supervisors. The one highly capable, qualified, experienced full-time supervisor was overwhelmed by the sheer volume of work. Though a second full-time supervisor was added in November 1968 and a third in July 1969, the new clinic building with sufficient office space was not finished until 1970. By then we had two very capable secretaries and there had been a change in administrative procedure. Each full-time supervising psychiatrist now had responsibility for one-third of the residents and one-third of the program. This made it possible to monitor the administrative problems, work load, and work quality of each resident. All initial write-ups were read and this enabled staff members to block inappropriate referrals to outside clinics and agencies. All this did not immediately affect the average number of patient visits, but a year later (1970) there was an increase from 110 to 144.7 and a further increase to 151.4 in 1971.

We think the reversal occurred because of changes in administrative style, increased office space, additional full-time psychiatric supervisors, and the passage of time required to season new supervisors and programs.

Equally important was the increased number and seasoning of volunteer supervisors and secretaries.

We are not trying to suggest that individual work volume is the only measure of residency training. We are acutely aware that nearly 200 patient visits per month (such as we had in 1965) may represent an overemphasis on clinical service that limits time for reading and seminars. But it is interesting that the year the residents complained most about "excessive" service obligations was the year they saw the fewest patients. If we deduct the 20 percent of patients seen by nonresidents, each resident averaged 160 patient visits per month; since each resident sees an average of 40 patients per month in group therapy, individual patient visits were actually 120. This seems an excessive load in a training program. On the other hand, 110 patient visits per month (such as we had in 1969) or 48, if we deduct the 20 percent seen by others and the 40 patients seen in groups, does not provide a sufficient clinical base for learning. This is too limited an experience in individual psychotherapy. It is our impression that a more extensive clinical experience with individual patients is necessary for resident training and development.

This was obviously not a controlled experiment, but it appears that a rapid increase in mental health professionals without a preceding increase in administrative structure lowers individual effectiveness. More bodies produce more work, but the increase is not proportional. In fact, a gross oversupply may even decrease the total number of patient visits. Even additional office space and supervisors will not immediately reverse the downward trend. In our experience, one year was needed before the addition of supervisors, office space, and changes in administrative style brought about an increase in the average number of patient visits.

CONCLUSIONS

A training program should provide at least one office per resident and staff member, a sufficient number of full-time supervising psychiatrists (one per seven residents), six to seven hours of individual and group supervision per resident per week, a reasonable administrative structure, and adequate secretarial and clerical help. Without these, individual efficiency is lowered. As programs enlarge, there are problems in morale that may cause bitter infighting between individuals and disciplines, and training suffers.

Enlarging a second-year training program from nine to 23 residents requires additional supervising psychiatrists and changes in administrative style. It is not possible to run a 23-resident program on an informal basis. Formal, even written, structure is imperative; consultation among staff members is no longer a luxury, but a necessity. It is also apparent that additions in supervising staff and office space are not immediately reflected by comparable increases in the average number of patient visits. There is a lead time of one or more years. Psychiatric residents first need to be "housed, fed, and cared for"; then they are able to "feed and care for" patients.

LETTERS TO THE EDITOR

"Dying with Their Rights On"

SIR: The old medical school saw of "dying in electrolyte balance" is not easily forgotten. Each of us remembers the compulsive chemo-clinician who, preoccupied solely with the patient's sodium, calcium, magnesium, potassium, and a host of other electrolyte levels, scarcely noticed the patient slowly slipping away. Even though the patient died, the fact that he was in perfect electrolyte balance when it happened was some sort of morbid clinical triumph.

This not-see-the-forest type of vision has now permeated psychiatry. In the zeal to impeccably protect the patient's civil liberties and rights, an increasing number of troubled and psychotic patients are what I choose to term dying with their rights on. I would venture that this also represents some sort of morbid clinico-legal triumph.

Three such cases have come to my attention here in Wisconsin during the past seven months since a federal court decision (*Lessard vs. Schmidt*) declared the state's commitment laws unconstitutional and prescribed a new, sole definition of committability. This definition is: "extreme *likelihood* that if the person is not confined he will do *immediate* harm to himself or others." Under this law, a 49-year-old anorexic woman starved herself to death; a 70-year-old man died a self-perpetuating, metabolic, toxic death; and a 19-year-old student, while unable to qualify for commitment under the new guidelines, was able to hang herself.

Each of these patients needed commitment; none qualified. Each outcome was entirely predictable. Each of these patients went to his or her grave with his rights entirely intact. (A similar case of a woman who "died after her civil rights were inviolably observed" was reported in *Psychiatric News* [1].)

The purpose of this letter is to solicit from the readers of the *Journal* similar cases so that they can be properly weighed in a central collection rather than by sporadic or anecdotal reports. The delicate task of balancing humane concerns with legal concerns in the commitment process is a legitimate concern of psychiatry. Certainly the right of the psychiatric patient to be free is a precious and important one, yet even that right must be reasonably weighed against the right of the patient and those around him to be protected from tragic and serious untoward effects of the patient's illness. The right to be protected has recently been overshadowed by our concern about the right to be free. *Both* are important. It seems to me that if there is a right to drown, for example, there must also be a right to be rescued.

Persons concerned with the patient's right to be sick and free have been more vocal and persuasive recently as the perpetual pendulum has swung from frank paternalism to frank abandonment; both of these extremes are distasteful. Now the voice of those who have seen cases in which the patient's rights but not his life were protected need to be heard also. A collection will speak more loudly than isolated instances. There must somehow be a proper balance between these two rights to prevent the several kinds of injustices possible.

Would any reader of the *Journal* who has knowledge of such cases please send them to me at the address below.

Are Methadone Withdrawal Patients Overprotected?

SIR: In working with heroin addicts who have subsequently entered a methadone maintenance program, I have seen the great physical difficulty patients have in withdrawing from methadone. Many of their symptoms seem to last for weeks after the initial withdrawal. For this reason, among others, many addicts are returned to the maintenance programs. It has been suggested that the abrupt withdrawal of methadone does not produce the excruciating subjective and objective symptoms usually associated with heroin withdrawal (1). Isbell and associates (2) described only mild withdrawal effects after abrupt cessation of methadone dosages higher than those now in clinical use. The fact that prolonged withdrawal from methadone causes as much discomfort as it does raises many questions.

Recently three patients who had had difficulty withdrawing from methadone gradually in outpatient and inpatient facilities were incarcerated. The jail authorities permitted methadone to be administered to these men, but it was withdrawn over a few weeks' time (about 30 days). Although none of the men knew of the others' experiences, all three had a similar response in that their symptoms upon withdrawal were minimal compared with previous withdrawals. They were in a situation where the anticipation of getting drugs was eliminated (obtaining hard drugs in a county jail is obviously difficult). The case reports of the young men follow:

Case 1. This 21-year-old white man with a two-year history of heroin addiction had been withdrawn twice previously on 30-day methadone programs. Each time marked symptoms of withdrawal began when he reached the dosage level of 15–20 mg.: he appeared pale and agitated and complained of insomnia, anorexia, and abdominal cramping. On one occasion he was hospitalized for withdrawal symptoms; they had become so severe that large doses of haloperidol (Haldol) and other sedatives did not relieve his insomnia and other symptoms. He was then placed in a methadone maintenance program for six months, receiving doses of approximately 120–150 mg. per day during this period.

While incarcerated, he was withdrawn from 120 mg. of methadone per day over a one-month period. A follow-up visit to my

office revealed that his insomnia had lasted only a few nights while he was in jail. In general, he was surprised at how easy this withdrawal had been.

Case 2. This 22-year-old white man, a Navy veteran, had had two heroin withdrawals while he was an inpatient at a Veterans Administration hospital. He had also had one 30-day outpatient withdrawal on methadone. The onset of significant withdrawal symptoms, he claimed, would lead him back to heroin use. He had been on methadone maintenance for six months, with an average dose of approximately 100 mg. per day, when he was incarcerated for an old offense.

While in jail, he was withdrawn from methadone over a 30-day period. Subsequent visits to my office revealed that he was astonished by how minimal his withdrawal symptoms had been while he was in jail. He appeared physically healthy.

Case 3. This 20-year-old white man had been addicted to heroin for approximately two years. He had previously had two 30-day outpatient withdrawals on methadone. He eventually started on the methadone maintenance program, cutting his own dosage from 100 mg. to an average of 60 mg. per day.

After his enforced 30-day withdrawal while in jail, follow-up visits to my office showed that he had had minimal subjective discomfort. Physically, he looked and felt better.

All three young men had repeated difficulty withdrawing from methadone. Whether the withdrawal had occurred on an inpatient or outpatient basis, they had complained of excruciating pain, insomnia, anorexia, and other symptoms, even when the withdrawal was gradual. Surprisingly, sudden withdrawal in jail produced milder, gradually subsiding symptoms.

One wonders if the medical profession has ignored the classic 1948 work of Isbell and associates (2) and the more recent article by Lipkowitz and associates (1) concerning withdrawal from methadone. Do we tend to overprotect and overtreat methadone withdrawal patients?

Chlorpromazine Contraindicated in Delirium Tremens

SIR: Understandably, a concise guide to the "Emergency Room Treatment of the Drug-Abusing Patient" by Dr. J.L. Chapel (March 1973 issue) is not the place to expound on conflicting therapeutic viewpoints. I feel, however, that the use of "100 mg. of chlorpromazine . . . intramuscularly every two to four hours" in the management of alcoholic delirium tremens (DTs) is contraindicated despite its current popularity.

There is some evidence that mortality is increased when this drug is used. Also, patients presenting with DTs have neuropsychiatric abnormalities that are often difficult to distinguish from or coexist with hepatic encephalopathy. Read and associates (1) demonstrated that patients with cirrhosis and hepatic encephalopathy are extremely sensitive to chlorpromazine, which depresses cerebral function or leads to clinical deterioration by hindering removal of blood ammonia.

As there is a predisposition to the development of jaundice in chronic alcoholics and others with hypoproteinemic states, one would not wish to further compromise hepatic functioning by administering chlorpromazine, which, even in 25 percent of healthy patients, leads to anicteric cholestatic jaundice.

Other undesirable effects that might complicate the medical management of already seriously ill and dehydrated patients (many with concomitant congestive heart failure, bronchitis, or emphysema) include tachycardia, quinidine-like electrocardiographic changes, hypotension, slight diuresis (by depressing the pituitary antidiuretic hormone and inhibiting renal tubular reabsorption), and lowering of the convulsive threshold (2).

As a much safer drug of first choice I would suggest diazepam (Valium), administered intramuscularly in doses of 10 mg. every hour or two until the patient is settled. The daily dosage should be from 30 to 50 mg. In addition to its tranquilizing properties, diazepam is an anticonvulsant and eliminates the need for diphenylhydantoin sodium (Dilantin). Paraldehyde, also safe, is rather unsuitable for injection and taken orally is a gastric irritant, especially to alcoholics, many of whom already have gastritis.

R. KALDA, M.D.
Toronto, Ont., Canada

SIR: Dr. Chapel's article contained, in my opinion, a rather serious error in recommending chlorpromazine as an alternate to paraldehyde in the treatment of delirium tremens.

The most impressive study in my 1970 review of the literature (1) was one by Golbert and associates (2) that compared four groups of patients treated for alcohol withdrawal. One group was treated with paraldehyde and chloral hydrate, one with alcohol, one with chlorpromazine, and one with chlordiazepoxide. The conclusion reached was that chlorpromazine, a phenothiazine, was comparatively ineffective and associated with serious complications.

Isbell and associates concluded in their classical paper (3) that the principal treatment of any drug withdrawal state was the substitution and then slow withdrawal of a pharmacologically similar drug. Alcohol belongs to the hypnotic sedative group of drugs and is pharmacologically quite dissimilar to chlorpromazine.

I am satisfied from my reading and can cite chapter and verse from the literature that if Dr. Chapel's advice to use chlorpromazine is followed there will be an increase in incidences of pneumonias, convulsions, and even deaths in the patients so treated. Although paraldehyde is regarded as sound therapy by some, many people experienced in the field feel that chlordiazepoxide, because of its high level of safety and, in contrast to paraldehyde, its absence of liver toxicity, is the drug of choice.

I might question the editorial policy that publishes such an article as Dr. Chapel's. It really has no new developments in it, nor anything that would not be properly described in any good textbook of psychiatry. It makes me wonder whether Dr. Chapel's position in academia, where one must publish or perish, had something to do with the paper.

GEORGE A. ROGERS, M.D.
Camden, N.J.

Dr. Chapel Replies

SIR: My thanks to Drs. Kalda and Rogers for pointing out my error in advocating chlorpromazine in the treatment of alcoholic delirium tremens. I can offer no valid excuse for this mistake and can only say I really should have known better.

There is no doubt that studies show chlordiazepoxide to be superior in the management of DTs and the paragraph in question should read: "For treatment the patient must be hospitalized. Fluid balance is critical; most patients will require several liters a day. On admission, 100 mg. of chlordiazepoxide hydrochloride (Librium) should be given intramuscularly, then 25 to 50 mg. orally every four hours thereafter, with total daily dosage not to exceed 200 mg. Diphenylhydantoin sodium (Dilantin), in doses of 100 mg. every four hours, may be added to prevent convulsions."

Steps are being taken to correct this error on the reprints.

It might be pointed out, however, that not "all good textbooks of psychiatry" advocate chlordiazepoxide over chlorpromazine. For example, Solomon (1, p. 482), Chafetz (2, p. 1017), and Freedman (3) still advocate chlorpromazine (Thorazine).

Is Tardive Dyskinesia a Drug Effect?

SIR: In his article "Tardive Dyskinesia: Side Effect or Not?" (April 1973 issue), Dr. John P. Curran raises the question of whether tardive dyskinesia is a side effect of the neuroleptic drugs or not. In a previous article (1), Ettinger and he raised the same question and suggested that an undiagnosed hepatic disorder may be responsible for motor abnormalities in drug-treated patients. However, liver dysfunctions were not detected in the three cases reported in the article under discussion.

Dr. Curran also states that there must be a temporal relationship between drug administration and dyskinesia in order to prove that this effect is really caused by a neuroleptic agent. In all three of his cases there was a clear-cut relationship between dyskinetic symptoms and treatment with neuroleptics.

He questions the validity of the conclusions of one of my publications (2), but he also mentions the findings that do support the same conclusions in a subsequent paper (3). He asks why drugs should be discontinued in the presence of dyskinesia when the administration of such compounds tends to reduce this condition. In a recent article published in this journal (4), I emphasized the danger of administering neuroleptics to patients with tardive dyskinesia because of the risk of further damaging the central nervous system.

Dr. Curran also questions the existence of tardive dyskinesia as a drug-induced clinical entity since the symptom may manifest itself after the withdrawal of medication and since it may subside after the reinstitution of treatment. This paradoxical phenomenon has been the object of considerable study on the part of investigators. A recent paper (5) dealt with this problem and offered an explanation based on known biochemical mechanisms.

After all this, I must raise the question: What has Dr. Curran contributed to prove that tardive dyskinesia may not be a drug effect?

Dr. Curran Replies

SIR: There are several issues regarding tardive dyskinesia: 1) What is it? 2) What is the relationship between it and neuroleptics? 3) How do we prevent it? and 4) How do we manage it? Dr. Crane addresses himself to the second and fourth of these questions.

Regarding the question of the relationship between tardive dyskinesia and neuroleptics, my article was written not to deny that there is a relationship between the two (my case reports clearly provide evidence that there is) but to question the wisdom of describing it as a *side effect* relationship. As physicians our instinctive reaction to a "side effect" is to immediately withdraw the offending agent. As I note in my article, and as I can testify from personal experience with other cases, this can be a serious error when we are dealing with tardive dyskinesia.

Dr. Crane asks what I have contributed toward proving that tardive dyskinesia may not be a drug effect. I hope that I have contributed to understanding it precisely as a drug effect, but not as a side effect. To some readers this may be an insignificant difference in emphasis, a mere quibble. Yet a close reading of Crane's December 1971 letter to this journal (1) compared with his October 1972 article (2) suggests, in my opinion, that he himself has come to appreciate this difference.

This brings us to the problem of managing tardive dyskinesia. In the same article (2) in which Dr. Crane discussed the danger of administering neuroleptics to tardive dyskinesia patients, he also made some qualifying statements that I would

like to quote at length because I find myself in substantial agreement with them:

> In some cases of severe mental disorder, however, the prescription of a relatively large amount of medication is required, even in the presence of pronounced neurologic impairment. The danger of aggravating the situation may be very real, but a clear understanding of the total clinical picture will put the clinician in a position to weigh on an individual basis the advantages as opposed to the disadvantages of drug therapy.

In general one has to consider four factors in managing tardive dyskinesia: mode of onset, severity, social disability, and presence of psychosis. If the onset of the syndrome is clearly in response to withdrawal of neuroleptics, as in my series, then the clinician should probably consider restarting the neuroleptic. If, however, the syndrome appears during treatment, then administration of thiopropazate may be indicated (3). Problems of severity and social disability were discussed by Dr. Crane in his article (2); I agree with his consideration of these matters. The presence of psychosis, especially an acute psychotic reaction, may render treatment with a neuroleptic imperative, overruling all other considerations (for example, see case 2 of my series in the April 1973 article).

While it is true that any psychosis can remit spontaneously, I honestly do not see how one can withhold a treatment of proved efficacy for fear of inflicting or aggravating putative brain damage. Of course, one should establish the minimal effective dosage as rapidly as possible, avoid the routine use of anticholinergics, as Klawans (4) suggested, and attempt to *slowly* withdraw the neuroleptic after the patient has been stabilized in a nonpsychotic state for, say, six months.

Dr. Crane deserves considerable credit for his tenacious, energetic pursuit of this puzzling clinical problem. But he has not, in my judgment, yet demonstrated that tardive dyskinesia is a neuroleptic side effect.

Freud and the Americans

SIR: It is not possible for me to reconcile the scene described at Putnam's camp in Roy R. Grinker, Sr.'s review of Nathan G. Hale, Jr.'s book *Freud and the Americans* (April 1973 issue) with the warm friendship, cooperation, and understanding conveyed in the letters between Putnam and Freud from 1909 to 1916 after this meeting as described in a book edited by Hale (1).

Would it be possible for Dr. Grinker to comment on this?

REFERENCE

PHYLLIS RUBINTON
New York, N.Y.

Dr. Grinker Replies

SIR: There is no question about Freud's antipathy toward Americans. It is commonly known that Jung wrote Freud during his visit here and indicated that if Freud minimized the "sexual" aspects of psychoanalysis the Americans would accept Freudian theories. Freud felt that Americans would eventually distort the field.

Secondly, Freud hated Woodrow Wilson, who could not put his 14 points through Congress after World War I.

Finally, in a personal communication to me while I was his analysand, Freud related that while at Putnam's camp he suffered from an intestinal disorder with cramps. People there saw him writhing on the ground and asked him, "How are you feeling, Professor Freud?" He answered, "Terribly," to which they responded, "That's too bad," and walked away. From this period, long before Jung's communication and Wilson's failure, Freud took a dim view of Americans. Was he correct?

Methaqualone as Aphrodisiac

SIR: The timely article "Quaalude Alley: A One-Way Street" by Drs. Bridge and Ellinwood (February 1973 issue) brings to light the misuse of methaqualone (Quaalude, Sopor, Somnafac, Parest).

An important reason for its widespread use among high school and college students is its reputation as a supposed aphrodisiac. This was reported by patients in Philadelphia nearly three years ago. Two years later, patients returning from distant colleges reported that "Ludes" were being promoted by their friends for the same purpose.

This drug is all too frequently supplied on request by physicians, sold by pharmacists with or without prescription, and shared by friends on the street. Patients have described serious loss of motor and intellectual control because of its sedative effect, while at the same time they deny that the drug has any sedative effect.

Philadelphia, Pa.

The Safety of Hypnoses

SIR: The article "An Episode of Acute, Self-Limiting Depersonalization Following a First Session of Hypnosis" by Drs. Wineburg and Straker (January 1973 issue) is very interesting and especially instructive. But I doubt that the authors drew the right conclusions.

Hypnoses, other than those for demonstration purposes, are performed frequently—quite often by laymen who are not very experienced. Years ago I had a patient who told me that as a teenager he had hypnotized most of his schoolmates without any apparent deleterious aftereffects whatsoever. Psychiatrists, psychologists, dentists, and others hypnotize many patients ev-

ery day. Psychiatrists and psychologists also perform daily hypnoanalyses. It is impossible to calculate the number of hypnoses and hypnoanalyses done every 24 hours that have no dire results. To the contrary, in 95 percent of the cases the effects are beneficial to the person undergoing hypnosis.

The last time an unfortunate aftereffect was reported from the Mt. Sinai Hospital in New York City was in the year 1949. E.D. Joseph and associates (1) reported that a patient had to undergo several other procedures after the hypnosis. It could not be proved that the psychosis which followed hypnosis in this very sick patient had any relation to the hypnosis itself.

I suppose I have performed about 10,000 hypnoses and hypnoanalyses in my practice, most probably many more. There was only one case in which an unforeseen and undesirable aftereffect resulted. In this case again it was not possible to definitely ascribe the regression of the patient to the hypnoses because she had not been hypnotized for a whole week before her regression.

Case 1. Although I had strongly advised that this patient should not be visited by her parents because of an unresolved oedipus complex, they did visit her. The father caressed the patient's arm in the same way he had when the patient was a child; there was a recurrence of her incestuous shame and guilt feelings. When the parents left, the patient immediately vomited and then regressed to the age of four, when she had had an accident and her mother had stayed with her constantly.

The patient demanded a pair of scissors at this time, but I was afraid to give them to her because she was suicidal. After a few days, however, I gave her a pair of old blunt scissors. She broke them apart and immediately became her actual age and in total contact with reality. The scissors had been her symbol for the "communion" between herself and her father. Had I given them to her when she had first demanded them the state of regression would most likely have terminated then and there. The patient had learned the technique of regression for therapeutic purposes through the hypnoanalytic sessions, but the regression itself was a consequence of her father's behavior.

This has been the only case in which a deleterious aftereffect occurred out of thousands of hypnoses and hypoanalyses (even here, however, the regression occurred only after hypnoses and not necessarily as their effect), and hypnoses are being performed daily by relatively untrained people without adverse consequences. Thus the statement of Drs. Wineburg and Straker that "hypnosis is a serious medical procedure and requires adequate safeguards" does not seem warranted.

I certainly deplore the use of hypnosis as a parlor sport, but there is no law against it.

EDITH KLEMPERER, M.D.
New York, N.Y.

Drs. Wineburg and Straker Reply

SIR: It is a pleasure to comment on Dr. Klemperer's critique of our report of a mishap following an uneventful episode of hypnosis.

We agree with Dr. Klemperer that most hypnotic trances are induced by untrained laymen and naïve nonpsychiatrists. We furthermore concur that morbidity is low and mortality is virtually nonexistent.

However, the aphorism ascribed to Pierre Janet expresses our concern: "The only danger of hypnosis is that it is not dangerous enough." The ease with which the trance is induced, combined with the lack of follow-up, has yielded the false assumption that hypnosis may be applied indiscriminately with never a possibility of harm.

Objective studies have shown significant frequency of sequelae to hypnosis. Josephine Hilgard (1) reported that "of 120 university students . . . 15 percent had some kind of reaction to hypnosis that endured for an hour or longer. . . ."

Dr. Klemperer's record of 10,000 cases with only one incident of morbidity is more a tribute to her skill in selection, preparation, and follow-up than a testimonial to the *absolute* safety of hypnosis.

Therapeutic Spiritual Experiences

SIR: It was refreshing to see Dr. Horton's article "The Mystical Experience as a Suicide Preventive" (March 1973 issue). More psychiatrists need to recognize the existence of man's spiritual nature and become able to use these experiences therapeutically. There are resources that we completely ignore if these experiences are automatically termed psychotic. I know of cases where a meaningful experience that could have given a patient great strength was negated by a skeptical psychiatrist.

The sense of complete forgiveness and acceptance by a loving Lord and by a group of like-minded people is the antithesis of a depressive state where the patient feels worthless and unloved. It is the "I'm ok" position of Dr. Harris (1, especially p. 237), because God makes a person ok.

Kildahl (2) documented the fact that there was a significant difference on the depression scale of the Minnesota Multiphasic Personality Inventory (MMPI) between a group of people who practiced glossolalia ("speaking in tongues") and a group matched in other respects who did not. (Glossolalia is a possible manifestation of the experience known as the baptism of the Holy Spirit; the practice is becoming quite common at this time, even in main-line churches.) In this study the glossolaliasts still maintained their feeling of well-being when tested a year later. Their assurance that God loved them had changed their lives. The study also showed that one group was not any more mentally healthy than the other: "Both groups contained persons along the continuum from the mentally ill to the remarkably mature."

I wonder upon what criteria the three patients whose cases were described in Dr. Horton's paper were diagnosed schizophrenic. In some institutions it is necessary only to mention religious ideas in order to have this label applied. Of course, it is extremely difficult to draw the line between what is culturally normal in some religious groups and what is frankly delusional. Perhaps some of us should have the honesty to admit we do not know how to distinguish this difference with certainty rather than dismiss everything nonmaterial as psychotic. Each religious belief should be evaluated in the context of an individual's

total personality, and the criterion for judgment should be the results of such experiences and whether they produce positive actions in the life. "You will recognize them by their fruits" (3).

In the area of drug abuse, for example, spiritual experiences have been found much more therapeutic in many cases than anything orthodox psychiatry has so far offered. Many drug addicts have been rescued by the organization founded by David Wilkerson (4), Teen Challenge. When members of this organization appear for court-ordered psychiatric examinations, however, they are very careful not to mention the religious reasons for their cure or they run the risk of being considered psychotic. The mere thought of a God who is accessible and influences people terrifies some psychiatrists into prescribing phenothiazines.

Psychiatrists should be aware of the resource of Teen Challenge, which has group homes and offices in many large towns. As Alcoholics Anonymous has helped many an alcoholic when orthodox psychiatry could not, so Teen Challenge helps young drug addicts.

Of course, there are those who think God tells them to blow up the White House, etc.; these individuals will be found to be disorganized in all parts of their life. There are others who believe God inspires them to positive action and in this strength they are able to overcome some of their problems. Whether the therapist himself accepts this or not, if he dismisses these beliefs as part of the patient's illness he is neglecting a valuable therapeutic tool and ignoring a large segment of society that uses these beliefs as the foundation for a productive life.

BOOK REVIEWS

Clinical Studies in Psychiatry, *by Harry Stack Sullivan, M.D., edited by Helen Swick Perry, Mary Ladd Gawel, and Martha Gibbon. New York, W.W. Norton & Co., 1973, 378 pp., $3.65 (paper).*

Rarely—rarely indeed—does a review assignment turn into an exciting and stimulating pleasure. This one does.

Carefully rereading Sullivan, here at his clinical best, was for me a rewarding, heartening, and at times even an awesome experience. Let me explain. The papers comprising this volume are the famous Chestnut Lodge lectures, delivered about 30 years ago to a brilliant gathering of psychotherapists and scientists that included, besides Dexter M. Bullard as host, Mabel Cohen, Edna Dyar, Frieda Fromm-Reichmann, Douglas Noble, Robert Morse, David Rioch, Alfred Stanton, Edith Weigert, Ben Weininger, and Mabel Wilkin. Certainly this stimulating, responsive—and at times, I'm sure, cantankerous—audience brought out the best in Sullivan. And this best is so good, so penetrating, and profound that even in the rereading it awakens a sense of awe and gratitude that one is still privy at this distance to such an observing mind.

Sullivan's commentaries on obsessionalism and hysteria seem to have worn best over the years. This may seem like an odd observation in that most of Sullivan's reputation seems to have come from his meticulous study of the schizophrenic syndrome. Perhaps because of my personal bias or perhaps because so much understanding of schizophrenic processes has followed his pioneering, the sections covering this material seem slightly precious today. Most present-day workers don't assess their schizophrenic patients as being quite so fragile as Sullivan did. His notes on paranoid developments, however, continue to be unmatched anywhere.

Also, it should constantly be kept in mind that these are clinical studies *within a psychotherapeutic framework* and that they are strongly reflective, at the same time, of interpersonal factors in the doctor-patient relationship. With this in mind, it is especially fascinating to compare Sullivan's observations with those of Frieda Fromm-Reichmann (1), his contemporary. Such a comparison brings into sharp focus the fact that Sullivan, the man, was challenged by and was exquisitely sensitive and alert to the aggressive factors in his patients, as compared to Fromm-Reichmann's feminine patience and calm as she waited for aggressive displays to run their course so that something more tender, and to her, more interesting, could take place in the relationship.

The publisher is to be congratulated on this easy-reading, pleasantly sized, and well-constructed paperback edition of its original 1956 hardback volume. This program of making Sullivan easily available to student and professional alike is no doubt making a very real contribution to the steadily growing enthusiasm for Sullivan's writings. Additional very real contributions are coming from Ralph Crowley of New York (2), who describes how Sullivan is coming to "almost secretly dominate American psychiatry," and from David Elkind (3), who notes that "the work of Harry Stack Sullivan, generally regarded as America's most original psychiatrist, is only now beginning to win widespread recognition."

The long, arduous efforts of the William Alanson White Psychiatric Foundation's committee on publication of Sullivan's writings—comprised of the late Mabel Blake Cohen, M.D., Dexter M. Bullard, M.D., David McK. Rioch, M.D., Otto Allen Will, M.D., and Helen Swick Perry, editorial consultant—are now paying off handsomely. These people deserve our continuing gratitude.

The uninitiated reader should be warned that Sullivan cannot be approached casually. His special language and system must be digested, and this requires serious scholastic endeavor. Be encouraged, however. It is worth the effort. An understanding of "security operations" alone, for example, can bring an important benefit to a whole psychiatric career.

KENNETH L. ARTISS, M.D.
Rockville, Md.

Beyond Freedom and Dignity, *by B.F. Skinner. New York, Alfred A. Knopf, 1972, 225 pp., $6.95.*

If Dr. Skinner had limited his call for a new science of man to a plea for study and research of human behavior by way of an objective, observational, and inductive methodology, few would disagree with his thesis. It is when he discourses in essentially philosophical areas that the romanticism of his thinking becomes apparent and the speculative nature of his utopia becomes controversial.

Between the proponents of determinism and free will there is no middle ground. The latter hold that man possesses the capability to deliberate, decide, and act independent of prior experience and is to be praised or blamed for his behavior. Dr. Skinner, the most prominent current behaviorist, rejects this view of autonomous man, holding that man is the consequence of the influence of the environment on the corporeal entity with its genetic endowment and potential for adaptation. Credit or blame for behavior should be placed on the environment.

The environment not only prods or lashes (i.e., stimulates) the individual, it also *selects.* Behavior is shaped and maintained by its consequences when these reinforce that behavior. Only by recognizing what the environment does to an organism, not only before but also after it responds, can the interaction between the organism and environment be understood in a more comprehensive way. Almost all living things act to free themselves from harmful contacts. Man does this through such processes as simple reflexes, conditioned reflexes, and respondent and operant conditioning.

Man's struggle for freedom is thus not due to a will to be free but to certain behavioral processes, "characteristic of the human organism," to escape from or to avoid "aversive" features

of the environment. Similarly, a man's dignity or worth is the measure of the credit given him for his behavior and is inversely related to the visibility of the causes of that behavior. Thus while "freedom" is an issue raised by aversive consequences of behavior, dignity concerns positive reinforcement.

Simply stated, dignity and freedom are concepts developed as a consequence of the exposure of the individual, experientially and in his evolutionary context, to his environment. They are part of the value system of a culture and are contingencies of reinforcement under which people live, comparable to those contingencies conceptualized as health, wealth, wisdom, order, and security.

Parenthetically, the irony might be noted that primitive man appears to have felt himself to be totally at the mercy of his environment, and, in the strictest sense of his position, Dr. Skinner returns to that concept—without the animistic beliefs. The ultimate value in his system is survival of the species.

Dr. Skinner dismisses psychoanalytic concepts as modern-day versions of the animism of primitive societies or the beliefs of possession by evil spirits. The division of the personality into id, ego, and superego and the personification of these three as being responsible by their interactions for the behavior of the man in whom they reside is comparable to animism from a scientific viewpoint. Skinner holds that the physical sciences made no progress until they gave up personifying things in this way and that the behavioral sciences, which are at least 100 years behind the physical sciences in this respect, will make no progress until they do likewise.

Feelings, both internally and externally stimulated, are to be viewed as by-products of the contingencies of survival. Behavior may be accompanied by good or bad feelings according to the consequences of the behavior, and feelings are generated in members of a social group by the reinforcers or values that persons in that group have come to use to effect behavior change or conformity. Thus an event that may occasion pain or anxious or aggressive feelings may condition an individual, or reinforce a tendency in him, to subsequently act in a particular way, but it is not the pain, anxiety, or aggression that causes him to do so.

While in some ways this represents a return to the postulates of psychologists in the early part of this century, it is in these not too subtle but vastly important distinctions that the essence of Dr. Skinner's disagreement with modern psychology and psychiatry lies. The conceptualization of feeling states such as anxiety, aggression, etc., as the causes of behavior is irrelevant and self-defeating in the pursuit of understanding behavior in a scientific way. In his terms, the feelings that accompany behavior have preoccupied behavioral scientists as the dominant factors to be understood and have displaced study of the really important factors pertinent to the science and technology of behavior.

It is when Dr. Skinner applies his theories to the management of a culture that he becomes less categorical in his statements, with frequent use of the subjunctive tense. In the chapters on the evolution and design of a culture, he becomes less certain about the practicality of totally reforming society. According to his definition, a utopia is a total environment in which all parts work together without conflict between the parts. But the single most important feature of a utopian design is that survival of the community can be made important to all its members.

Recognizing the problems of implementation, Dr. Skinner suggests that perhaps the development of better practices should be undertaken in piecemeal fashion. For example, solving the problem of deserters and draft dodgers (who, incidentally, constitute only a small portion of their cohort) requires changing the contingencies that induce young people to behave in given ways toward their government. But he does not specify any particular means. Nor does he mention that changing the contingencies for one set of individuals might result in the emergence of comparable or other problems among some or all of the larger group who, under present contingencies, present no such problem. Similarly, to solve the problem of war, the answer is to be found in changing the circumstances under which men and nations make war.

Despite statements of the difficulties at hand, Dr. Skinner returns to the theoretical possibility of intentionally designing a presumably better, if not utopian, culture. He recognizes that such a society would not necessarily be liked by those persons who were "re-formed" but would be liked by their successors who live in it. Yet the latter group would necessarily also be the product of an older culture. Moreover, he recognizes that the designer, and presumably the master, would himself be culture-bound. Given the author's premise that man is the product of his biological evolution modified by his environment and that he has no independent power in a scientific sense to modify it, I have the impression that either he realizes this and his advocacy of a great design for a perfect world is presented somewhat with tongue in cheek or else he is still struggling with his scientific concepts.

Dr. Skinner prepares for attack by his critics by reminding the reader of the great scientific innovators who were rejected in their own day. In either case, Dr. Skinner displays his considerable skill in writing a romantic script under the guise of science—a form of science fiction. Twenty-five years ago he wrote a comparable fantasy in *Walden Two* (1), whose remarkable appeal over the years appears to be due to the emotions or feelings aroused in its readers. This book is a natural how-to sequel.

The author is on more solid ground in the early portion of this latest work. There is considerable appeal for a new science of behavior based on objective observations of the interaction of man and his environment, on which there would be based a new technology of behavior. In the later portion his formula for a comprehensive, systematic approach to attain behavior modification in, and control of, others raises many interesting questions. For example, whom but Dr. Skinner would Dr. Skinner accept as this absolute controller of the culture? And anyway, hasn't someone already written about how it will be in 1984?

Hartford, Conn.

Why People Kill Themselves: A Summary of Research Findings on Suicidal Behavior, *by David Lester, Ph.D. Springfield, Ill., Charles C Thomas, 1972, 353 pp., $14.75.*

In reviewing this book I will try to perform a service to the reader by clarifying what it *is* as opposed to what it seems to be. The primary title suggests that the book provides answers to the important question "Why do people kill themselves?" In fact, there are none. The subtitle is what the book is really about. And as the author himself concludes, after an exhaustive but by no means complete review of the literature, the research is of generally poor quality, and the results are inconclusive. In fact, in the author's opinion, suicide research is so outstandingly poor that the causes of this phenomenon should in themselves be explored.

The flyleaf states that "all available research is reviewed. . . ." This is not true. In the preface the author cites several limitations of the book, among which is that it is restricted to

writings in the English language. The most important limitation, however, is that the author has relied upon the bibliography provided by Farberow and Shneidman for the literature up to 1957. The flyleaf also states that the author "provides a critical and unbiased view of research that has been conducted into suicidal behavior." In my opinion, the author does reveal a bias, and he seems to accept, uncritically, the bias of Farberow and Shneidman, whose incomplete bibliography is the one he uses.

The author's bias, for the benefit of the reader, is that research (good, valid, acceptable) is defined as a project that has a hypothesis. This hypothesis must then be tested by an experimental design that includes a control group and an experimental group. The hypothesis is then either advanced, rejected, or judged irrelevant to the data and analysis. The unseen and unspoken bias is that a single case study is not research. This is an unfortunate and damaging bias, because it eliminates some of the most valuable sources of data relevant to the question "Why do people kill themselves?"

It is to the author's credit that he stumbles upon this realization himself, in his last answer to his last question in the book, "Where do we go?" He answers that the two areas which are most promising for suicide research are the childhood experiences of the suicidal individual and his social relationships. But the richest source of data in these areas is the psychoanalytic literature, in which case studies do not qualify, somehow, as research. If, after reviewing one bias of what constitutes acceptable suicide research, the author succeeds in looking in the direction of detailed case studies and long, painstaking analytic observation, he will have performed a valuable service to himself and to his potential readers. It is, after all, a sobering experience to review and summarize a large part of the world research on suicide and find it a hodgepodge of crude work!

To illustrate, the references include two articles by Norman Tabachnick: "Interpersonal Relations in Suicide Attempts" and "Comparative Study of Accidental and Suicidal Death." Yet there is no reference to his article on "Countertransference Crisis in Suicidal Attempts" (1). This last paper is a penetrating examination in depth and detail of an interpersonal relationship that led to a suicide attempt. There are other important omissions that the author is either unaware of or does not explain.

My own bias is the psychodynamic-psychoanalytic orientation. I would have preferred that the author omit the research on the correlation of suicide with phases of the moon, for example.

The references are listed alphabetically at the end of the book, by author. There is no topic reference or index and therefore no way the reader can easily find a particular summary he is looking for.

In summary, the book reflects much that is unfortunate in the area of suicide research. However, it does represent a quick way to review a large part of what is considered suicide research by some researchers in the field. Fortunately, the author recognizes the inadequacy of this type of research on suicide and begins to look in more promising directions: the in-depth study of the early childhood and personality development of the individual. The barrier here is the unwillingness of most of us to explore the roots of our own self-destructiveness. It is just too anxiety-provoking!

VICTOR BLOOM, M.D.
Detroit, Mich.

Biological Basis of Alcoholism, *edited by Yedy Israel, Ph.D., and Jorge Mardones, M.D. New York, John Wiley & Sons, 1971, 442 pp., $19.95.*

In this volume a selected group of 29 researchers, all recognized experts in their respective fields, analyze the different approaches and recent findings of their work in an effort to establish a scientific basis for the understanding of alcoholism. These investigations begin at the subcellular and cellular levels and increase in complexity and level of integration to the organ, the individual, and the society. The result is a detailed and exhaustive review of the biological basis of alcoholism, documented by extensive references.

While stressing the physical aspects of alcoholism, the contributors recognize that psyche and soma cannot be separated and that there is an interaction of alcohol with the biological system, the genetic characteristics of the system, as well as with psychological and cultural factors.

Some of the specific topics treated are the different enzymatic processes that metabolize and control the rate of alcohol elimination, the effects of alcohol on the nerve cell, the mechanisms of adaptation to the continuous presence of the drug, and the effect of substances other than ethanol that are present in alcoholic beverages. Also discussed are the relationship between chronic alcohol ingestion and liver, heart, and pancreatic damage, the nutritional deficiencies in the alcoholic, the role of heredity in determining the appetite for alcohol, the question of how the availability of the drug affects the rate of alcoholism in a population, and the psychological and pharmacological basis for the treatment of alcohol dependence.

Perhaps the most interesting thing about this book is the internationality of the contributors, who came from Denmark, Chile, Canada, the United States, and Finland. The fact that they do not arrive at any hard conclusions testifies to the scientific integrity of this research as well as the complexity of the problem of alcoholism. This book should be in the library of anyone doing research in or studying, in depth, the nature of alcoholism.

FREDERICK LEMERE, M.D.
Seattle, Wash.

The Problematic Self in Kierkegaard and Freud, *by J. Preston Cole. New Haven, Conn., Yale University Press, 1971, 229 pp., $7.50.*

J. Preston Cole's book is a profoundly erudite work. It treats an issue—the *problematic* self—that is of immense and urgent importance to contemporary man. Regretfully, it is strictly confined to the Christian perspective and proffers the ultimate resolution of man's existential despair in the religion of the Son. "Christ," Cole affirms, "is the paradigm of selfhood, the dialectic incarnation of God. In Him is fully manifest the dialectic of the finite and infinite, the temporal and the eternal, necessity and possibility. In short, he is the paradigm of the relationship between man and God" (p. 228).

And so He is! But hath not God other Sons besides? Many, even as I am persuaded, believe as much. But clearly Cole is not to be counted among them.

In *The Self in Transformation* (1) Herbert Fingarette pursued a thesis akin to that of Cole's, admittedly on a simpler plane, and he found great spiritual nurture in the Sons of the East: Confucius, Lao-tse, Zen, etc.

Cole composed his work in the hope that "in this way new light has been thrown both on Freud and Kierkegaard, or that

at least Kierkegaard will have been made intelligible to Freudians, and Freud to Kierkegaardians, who seem eternally at war."

Should the Freudians, and other psychiatrists, too, read this book, as I would heartily recommend, they will most certainly learn a good deal about Kierkegaard's thoughts and teachings, for Cole is a master expositor and superbly skilled in the dialectics of metaphysical arguments. But as for reconciling Freud and Kierkegaard and making peace between these nominal antagonists and their followers, much doubt is warranted.

And yet, are they really at war? Cole tries hard to portray an antagonism that is in fact interpretive rather than real. Freud is "fitted" to the procrustean thesis of Cole's argument. Cole interprets what he quotes from Freud's writings to fit his own presuppositions. Furthermore, while Cole has read much of Freud's writings, he quite evidently has only a literal, not a clinical, understanding of Freud's theories.

But why all this pother about the similarities and divergences between Kierkegaard and Freud? They both dealt with the self, but the one was a positivist psychiatrist, while the other was a metaphysical theologian. Freud had little regard for philosophy and even less for metaphysics. Kierkegaard knew no science.

And yet, paradoxical as it may seem, it can be said that "Kierkegaard carries on from where Freud left off." Freud entertained no illusions. He brilliantly illuminated the self of the here and now. He knew of no transcendence. He mocked the oceanic feeling of the self in transport. Kierkegaard, on the other hand, was ultimately concerned with the "other self," with the second self that transcends the immediate self.

> To the immediate self, which is determined by its own natural desires or drives, there comes the awareness of another mode of being peculiar to man. Dreamingly, Spirit becomes manifest to the individual as a possibility, *his* possibility. Thus his true being, Spirit, is projected as his own reality. An unrealized reality, a reality which is as yet only a possibility (p. 15).

This may appear to some as mystical, but the psychiatrist, and notably the psychoanalyst, should readily perceive the profound validity of this affirmation. They can attest out of their own experience that "in the realm of human existence there is the possibility of 'a second becoming within the first becoming,' as Kierkegaard puts it" (p. 23).

It is not possible in a brief review to do full justice to this work. It is erudite, subtle, gracious, affirmative in spirit, and inspiring. It presents a comprehension of the meaning of man's life that cannot be but antidotal to the prevailing cynicism and despair. The essence of the book is not easily grasped; but it merits careful study and, when understood, will prove immensely rewarding. It speaks in a vernacular alien to the intelligence accustomed to the jargon of positivist science, but it carries instruction that cannot help but enlarge our understanding of existential man, man's singular potentials, and man's unique existence.

Fundamentals of Electroencephalography, *by Kenneth A. Kooi, M.S., M.D. New York, Harper & Row, 1971, 249 pp., $12.95.*

Dr. Kooi, Professor of Electroencephalography at the University of Michigan Medical School, has written an unusual book reflecting his many years of work in electroencephalography and his indebtedness to Dr. B.K. Bagchi. The book is intended as "a compact source of information about human electrocerebral phenomenology." The orientation is strongly clinical, definitely more American than European in flavor, and with interpretation well rooted in neurophysiology. The presentation of material is functional rather than disease oriented, an approach that yields a format which is quite different from that of any other book on electroencephalography.

One is reminded of Grey Walter's old point about descriptive terms in science. The now obsolete meaning of "astrology" was usurped by pseudoscience, leaving "astronomy" as a less accurate term. And "electroencephalography" would be better termed "electroencephalology." The point is that electroencephalography, as an increasingly routinized clinical tool, had acquired a pejorative connotation, especially among neurologists. This book indicates that electroencephalography is more than just a technique and that the body of knowledge, still rapidly growing, constitutes a field in its own right. The practical and definite clinical value is the theme of this book, but the approach is well suited to a broad and orderly survey of the phenomenon of the electrical activity of the entire brain, both spontaneous and evoked.

The organization, as one would expect, is different. V.A. Basman has contributed eight pages of basic electrical principles. If the reader knew nothing of this, the material, while accurate, would be too concise to be helpful. This material is readily available elsewhere, and it could have been omitted without decreasing the value of the work. In a book with "fundamentals" in the title, a section on instrumentation is imperative; the eight pages devoted to this subject simply are not adequate. The references (all given by chapter) should have included Hill and Parr's *Electroencephalography* (1, 2).

The section on sampling electrical fields is fair and judicious, although the inclusion of actual EEG samples would have given added emphasis. The Michigan electrode array is yet another modified 10–20 system with more electrodes than are generally used in the United States. The serious reader would be well advised to make a plot of electrode placements for working out the sometimes unusual montages employed. The actual illustrations, based on unretouched and remarkably clean tracings, are derived from eight-channel equipment and only rarely show activities from the additional electrodes. Many figures are based on a joined ear-reference technique, which is adequate to the point being illustrated; the text contains a brief but appropriate caveat.

Part 2 of the book, an excellent section, deals with the basis of EEG interpretation. There is a factual review of the genesis and regulation of the normal, spontaneous electrical activity of the brain, followed by its many variations and modifications, which may have some significance. Thus alterations in electroencephalographic voltage, frequency, symmetry, morphology, abundance, and distribution, paroxysmal or steady, are treated in a *general* way without specific regard to definite clinical correlates. This establishes a broad base of normality according to age and level of consciousness, with an enlightened attitude toward minor variations. It is enriched by a new and important dimension which receives subsequent emphasis—that of the changes induced by stimulation as determined by careful study of evoked responses. The relation to mental processes is discussed.

Nearly half of the book (part 3) is devoted to the manifold

ways in which the aforementioned features are modified by and related to the *specific* conditions affecting the central nervous system. These include, of course, the epilepsies, tumor and trauma, circulatory disease, developmental and degenerative disorders, infections, and metabolic and endocrine disturbances. The description, while often rather brief, generally goes beyond the purely phenomenological and indicates concern with the reasons for the abnormalities. Alterations of evoked responses are included as another parameter of evidence to supplement the changes in spontaneous activity. The chapter on psychiatric disorders is brief and pessimistic, while the one on neuroactive drugs is much more complete and very pertinent to psychiatrists.

Dr. Kooi's book is a distinctly personal work. This is reflected in the appreciable data from his own laboratory that bears on the clinical electroencephalographic features in brain tumor and epilepsy, plus the contribution of evoked responses. It is not meant to be a how-to book, nor is it particularly useful as a ready reference, for example, to the electroencephalographic correlates of specific disease states. In review of this, the references to necessary supplementary works are curiously incomplete. I would have added at least a dozen fundamental titles to the brief list of general references, the first of which would have been Kiloh and Osselton's *Clinical Electroencephalography* (3) for general orientation and the second *Electroencephalography and Cerebral Tumours* (4), without which no electroencephalographer can avoid disaster.

In summary, this new type of EEG book does indeed present the fundamentals of EEG. It will be of particular interest to electroencephalographers and technologists who are concerned with training programs. It is quite possible that the book will be a good introductory text to the field of electroencephalography, on which additional basic reading and practical laboratory experience will build a degree of understanding not achieved by more traditional approaches.

CHARLES E. HENRY, PH.D.
Cleveland, Ohio

Children of the Rich, *by Burton N. Wixen, M.D. New York, Crown Publishers, 1973, 209 pp., $5.95.*

This book addresses itself to that relatively small and almost forgotten group—children of the very rich. The author refers to them as CORs, by which he means those youngsters and their families who have such large amounts of money that they are denied little if anything of a material type.

He feels, and probably rightly so, that CORs are often "a wasted resource," and he uses the term "dysgradia" to explain why many of them do not mature emotionally as well as they should.

He cites several case examples from the financial and business world and also from the stage and screen. Dysgradia, as used by Dr. Wixen, refers to an identity problem. These children are often raised by nursemaids, given all the material things they want, and have trust funds ensuring them a sizable income. The middle-class values of hard work, upward striving, etc., are meaningless to many of them. These youngsters can be compared, as others have done, more to lower socioeconomic youngsters than to those from the middle class. While it is true that some CORs succeed, many lead aimless lives.

The author has at least two major suggestions. One is that the therapist should not try to impose his middle-class values on the COR patient. He should set his sights differently and aim for a firmer identity for the patient and even, where possible, his commitment to a reasonable cause. Second, he raises the idea of a CORs Anonymous, which would bring together this rather isolated group of individuals and help them gain strengths and new ideas from the other members.

All in all, this is an interesting, well-written, but not rigidly scientific book. Relatively few of us in the mental health professions have treated such people, but the book gives some valuable suggestions about the problems to be anticipated. It is enjoyable reading even if one does not have such patients and could be helpful if one does. Even such matters as transference, countertransference, and fee schedules are dealt with and are well worth considering.

STUART M. FINCH, M.D.
Ann Arbor, Mich.

Cruel, Poor and Brutal Nations, *by John Cawte, M.D., Ph.D. Honolulu, University Press of Hawaii, 1972, 177 pp., $9.50.*

This psychiatric study of aborigines living on a small island off the northern coast of Australia is an important attempt to deal with a usually neglected problem. What can we do, as psychiatrists and as concerned citizens, to assess and mitigate the culture shock of people who are leapfrogging centuries of technological development in a single generation? How much change can the human organism incorporate? What is the optimal rate of change? Can anything be done to minimize the adverse effects of such change?

The author, Associate Professor of Psychiatry at the University of New South Wales in Sydney, is a Distinguished Fellow of the American Psychiatric Association and a frequent visitor to this country. He also has an advanced degree in anthropology. For ten years he has spent his vacations living with different groups of aborigines in the Australian outback. He has also done field work in Papua, New Guinea. In Australia he is an acknowledged expert on problems of the aborigines and a frequent spokesman for their causes.

The book describes an interdisciplinary study of the aborigines living on Mornington Island in the Gulf of Carpentaria. Psychiatrists, psychologists, anthropologists, a biologist-geneticist, and a geographer combined efforts in what became a brief version of psychiatric field surveys such as Alexander Leighton did in Nigeria and Nova Scotia. A modified Cornell Medical Index was included in the psychological testing.

Especially interesting are the chapters on the Kaiadilt subgroup, which was at the edge of extinction and showed a high rate of serious mental disturbance. Also important is the author's discussion of the cycle of ecological and geographical changes, interpersonal disturbances, and intrapsychic malfunction. There are two chapters on the problems among children that are well worth reading.

The author's writing style is clear and concise. Several pages

of pictures make the setting more real. The book is strongly recommended to those psychiatrists with an interest in ethnopsychiatry, problems of rapid technological change, and majority-minority group relationships. Racism is an important ingredient in the last, and the author has sarcastically chosen for the book's title the description applied to these aborigines by an early explorer. On Mornington Island, as elsewhere, racism has compounded the other problems faced by these people. The book also serves as a useful model for brief, economical psychiatric field research. Finally, by making specific, realistic recommendations for assisting these people, the author illustrates that such field research may have useful consequences for the people under study.

E. FULLER TORREY, M.D.
Rockville, Md.

La faim et le corps: Une étude psychanalytique de l'anorexie mentale, *by Evelyne Kestemberg, Jean Kestemberg, and Simone Decobert. Paris, Presses Universitaires de France, 1972, 301 pp., no price listed (paper).*

Although written from a psychoanalytic approach, this fine book on anorexia nervosa (which is called "mental anorexia" in France and Italy) can be read profitably by nonanalysts as well—for example, by pediatricians, whom the subject interests greatly. The authors, all members of the Paris Psychoanalytical Society, have included a comprehensive review of the psychoanalytic principles and concepts having to do with the development of object relations in the child.

The authors begin with a general chronological review of the literature on anorexia, underlining the main contributions of the more important works. This is followed by a careful, detailed clinical description of three adolescent patients, the initial interviews with them, and their family constellations. The phenomenological acuteness of observation and the richness of language and stylistic quality make this section fascinating reading. The section is completed by a clinical psychoanalysis identifying the constants in the patients' personality organization that became evident in the course of psychotherapy.

The third part of the book consists of metapsychological hypotheses pursued in depth about aspects of hunger and the body in the anoretic personality. These hypotheses offer major contributions to the understanding of the psychoanalytic theory of masochism, the death instinct, and the paradox of a particular autoeroticism described as the orgasm of hunger, in which a basic need such as hunger does not serve as a defense against uncaring self-destruction.

This study is essential for anyone wanting to really understand that paradoxical and mysterious malady, anorexia nervosa.

SAMUEL I. STONE, PH.D.
Boston, Mass.

The Treatment of Alcoholics: An Evaluative Study, *by Sidney Cahn. New York, Oxford University Press, 1970, 239 pp., $7.50.*

This book reviews the services and treatment programs available for the management of alcoholics in the United States, under the auspices of the Cooperative Commission on the Study of Alcoholism. As such, it is a very informative and useful text. However, the title is misleading, and if the reader expects a full evaluation of the various management procedures in the treatment of alcoholics, he will be disappointed.

Although a multicausal approach is emphasized, the author's description of the present status of the causative factors in the production of alcoholism is incomplete and does not include, for instance, reference to the many neurochemical and neurophysiological studies done in the field. The contrast between the different psychopathological models of causation is, however, well done.

Although the various forms of group therapy are described, the author gives little detail of their actual mechanisms and objectives. In addition, the place of individual psychotherapy is not given the attention that it deserves. There is also some overlap and repetition in the section covering treatment methods.

There are some good data on the association of social strata factors and alcoholism, the welfare programs available, and the variations in the way courts handle each individual case by area and social stratum. The importance of welfare programs is also rightly emphasized and discussed.

Little mention is made of the usefulness of the detoxification center in alcohol treatment programs. The center at the St. Louis State Hospital complex has adequately demonstrated the importance of such centers. The importance of psychiatric and medical complications that may be associated with or follow chronic alcoholism and that may determine the way an alcoholic is handled is not considered.

I wish that the author had given more definitive conclusions and suggestions, based on his experience with the present programs, as to what steps should be taken in the future. There is, in fact, a chapter of summation and recommendations, but it is out of proportion with the large amount of work that has been put into the rest of the book.

There are many useful references, by chapter, to books and other publications, but these are predominantly sociological or epidemiological in nature.

This book should prove most useful to administrators and directors of large community alcohol treatment programs, particularly where such programs are under development.

Here Comes Everybody: Bodymind and Encounter Culture. *By William C. Schutz. New York, Harper & Row, 1971, 292 pp., $6.95.*

The author is a director of the residential program at the Esalen Institute, which indicates that he can speak with considerable authority about encounter groups and related phenomena. As a professional, he was trained in psychology.

The goal of the book, as presented, is "encounter as a culture with its accent on new awareness of the body that is critical to encountering." The book describes "rolfing" and other techniques that propose to reveal the intimate connections between bodily expression and how we think. Elsewhere on the dust jacket the book is described as a "manual for group leaders, a comprehensive, theoretical foundation for the encounter method, and a road map for applying the way of life everywhere."

Encounter culture has its values, as stated by the author, and one can take them or leave them. Much emphasis is placed upon honesty in dealing with others and self-awareness regard-

ing feelings. The author seems to see this as coming about a good deal more easily than a psychiatrist would, especially for those who experience conflict when they become aware of unwanted impulses and feelings. As a theoretical approach to behavior and culture, encounter as presented seems simplistic in its approach to the psychosomatic area and structure of the mind. The exposition of rolfing techniques in approaching mind-body problems will seem both naïve and uninformed to the medical reader. The application of some of these techniques, as described in the book, to patients who have clinical disturbances would seem imprudent at best and unsupported by data that would enable us to discriminate those for whom such techniques would be harmful. As a manual for encounter group leaders the book seems unscientific, in that it makes claims that are unsupported by evidence, and it seems irresponsible in its approach to the problem of selection of leaders and participants in order to negate, as much as possible, the chance of harm to participants.

In a recent, carefully done, controlled study of encounter groups, Yalom and Lieberman showed that 7.5 percent of the participants became casualties as a result of their participation in these groups (1). A disproportionate number of these casualties came from groups led by persons with characteristics described as desirable by Mr. Schutz (high stimulus input, aggressivity, charisma, supportiveness, intrusiveness, and individual—as opposed to interpersonal or group—focus). Dr. Yalom also pointed out that there are people who approach these groups with a low self-concept and unrealistically high expectations and anticipations of change, and it is among these persons that one finds a disproportionate number of casualties. In Mr. Schutz's view, it is the patient's responsibility to screen himself and to look out for himself. This seems to be an undesirable attitude to take when it is clear that many vulnerable people may be tempted to use this technique in an attempt to solve their personal problems. Somehow, it does not seem to be part of the encounter ethic to take such vulnerability into account.

For all of the foregoing reasons, I cannot recommend this book as a scientific document. It is interesting as a presentation of the kind of things that are a part of the encounter phenomena.

FRANCIS J. KANE, JR., M.D.
New Orleans, La.

The Nurse's Role in Community Mental Health Centers, *by Carol D. DeYoung, R.N., M.S., and Margene Tower, R.N., M.S. St. Louis, C.V. Mosby Co., 1971, 112 pp., $4.90 (paper).*

What is the role of the nurse in the five basic components of the community mental health center? What is considered to be the preparation for the nurse in these areas? What are the possible ways of implementing the results of this study in Colorado? Briefly, these were the questions that a task force of the Colorado Nurses' Association asked a variety of mental health professionals who represented all disciplines. This book is a report of their study. It presents a report of the issues raised by such questions as these in a more candid way than most current literature does.

The authors have raised some very cogent and relevant issues that require examination by all professionals. For example, they point out that a total system change will be needed if nurses are to become an integral part of the community mental health team. In present programs, nurses are still only fully accepted as the member of the inpatient team who gives medications. It seems to me that the authors imply that nurses, who have worked for years to become respected members of inpatient services, are now experiencing what they view as major resistances to their attempts to move into other areas of mental health care.

The authors make it clear that the responses made by the nonnursing subjects in the study indicate that the nurse must aggressively make a place for herself or be left out of the community mental health scene entirely. How else is one to interpret the reaction of one psychiatrist who said that he had never had reason to talk about the role of the nurse in a community mental health center, or the view of the technicians that the nurses' role is much like their own? A social worker's view of the community mental health nurse was tied directly to public health nursing and the care of chronically ill patients. A psychologist did not consider additional formal training beyond basic nursing preparation as necessary for nurses!

The nurses interviewed had difficulty conceptualizing the uniqueness of nursing, although they could describe many nursing activities. Early in their deliberation, discussion came to a dead end, but later they spoke of the "it" or "x" factor in nursing. They felt that this x factor was composed of three elements: regard for the patient, a practical orientation, and the ability to be satisfied with helping.

The final chapter concerns itself with what I consider to be two of the most important issues facing nursing today: primacy of prevention and the role of social action in nursing. The authors propose a model that incorporates "social action as a part of primary prevention as well as caring for the illness component." They also stress the vital importance of nurses becoming skilled in power politics techniques.

In summary, this book helps the reader toward a greater clarification of the nurse's position in present community mental health centers. There is also elucidation of issues that must be considered if the nurse is to become a fully integrated member of a community mental health team. The volume has special relevance for nursing students and nurses who are developing new roles in community mental health nursing. However, the sample is small and the study is a localized one, and therefore it should be replicated on a much broader scale. The book challenges the reader to take another look, perhaps a new look as well, at community mental health, particularly at the quality *and* quantity of the team.

The Principles of Medical Ethics
With Annotations Especially Applicable to Psychiatry

The Principles of Medical Ethics With Annotations Especially Applicable to Psychiatry

This statement was approved by the Assembly of District Branches and the Board of Trustees of the American Psychiatric Association at their May 5–6, 1973, meetings, upon recommendation of the Committee on Ethics.[1]

FOREWORD

ALL PHYSICIANS should practice in accordance with the medical code of ethics set forth in the Principles of Medical Ethics of the American Medical Association. An up-to-date expression and elaboration of these statements is found in the *Opinions and Reports of the Judicial Council* of the American Medical Association (1). Psychiatrists are strongly advised to be familiar with these documents.[2]

However, these general guidelines have sometimes been difficult to interpret for psychiatry, so further annotations to the basic principles are offered in this document. While psychiatrists have the same goals as all physicians, there are special ethical problems in psychiatric practice that differ in coloring and degree from ethical problems in other branches of medical practice, even though the basic principles are the same. The annotations are not designed as absolutes and will be revised from time to time so as to be applicable to current practices and problems. Although the material appears in this form for the first time, it is derived from the work of many committees and task forces over the years.

Following are the AMA Principles of Medical Ethics, printed in their entirety, and then each principle printed separately along with an annotation especially applicable to psychiatry.

[1] The committee included C.H. Hardin Branch, M.D., Chairman, Herbert Klemmer, M.D., Robert A. Moore, M.D., Robert P. Nenno, M.D., Alex D. Pokorny, M.D., Charles D. Prudhomme, M.D., Joseph S. Skobba, M.D., and Gene Usdin, M.D. William P. Camp, M.D., and Byron A. Eliashof, M.D., were members of the subcommittee that aided in the preparation of these annotations, and William A. Bellamy, M.D., was special consultant.

[2] Chapter 8, Section 1 of the By-Laws of the American Psychiatric Association states: "All members of the American Psychiatric Association shall be bound by the ethical code of the medical profession especially defined in the Principles of Medical Ethics of the American Medical Association."

PRINCIPLES OF MEDICAL ETHICS, AMERICAN MEDICAL ASSOCIATION

PREAMBLE

These principles are intended to aid physicians individually and collectively in maintaining a high level of ethical conduct. They are not laws but standards by which a physician may determine the propriety of his conduct in his relationship with patients, with colleagues, with members of allied professions, and with the public.

SECTION 1

The principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion.

SECTION 2

Physicians should strive continually to improve medical knowledge and skill, and should make available to their patients and colleagues the benefits of their professional attainments.

SECTION 3

A physician should practice a method of healing founded on a scientific basis; and he should not voluntarily associate professionally with anyone who violates this principle.

SECTION 4

The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.

SECTION 5

A physician may choose whom he will serve. In an emergency, however, he should render service to the best of his ability. Having undertaken the care of a patient, he may not neglect him; and unless he has been discharged he may discontinue his services only after giving adequate notice. He should not solicit patients.

SECTION 6

A physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care.

SECTION 7

In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him, or under his supervision, to his patients. His fee should be commensurate with the services rendered and the patient's ability to pay. He should neither pay nor receive a commission for referral of patients. Drugs, remedies or appliances may be dispensed or supplied by the physician provided it is in the best interest of the patient.

SECTION 8

A physician should seek consultation upon request; in doubtful or difficult cases; or whenever it appears that the quality of medical service may be enhanced thereby.

SECTION 9

A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community.

SECTION 10

The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community.

Principles with Annotations

Following are each of the AMA Principles of Medical Ethics printed separately along with an annotation especially applicable to psychiatry.

PREAMBLE

These principles are intended to aid physicians individually and collectively in maintaining a high level of ethical conduct. They are not laws but standards by which a physician may determine the propriety of his conduct in his relationship with patients, with colleagues, with members of allied professions, and with the public.[3]

SECTION 1

The principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion.

The patient may place his trust in his psychiatrist knowing that the psychiatrist's ethics and professional responsibilities preclude him from gratifying his own needs by exploiting the patient. This becomes particularly important because of the essentially private, highly personal, and sometimes intensely emotional nature of the relationship established with the psychiatrist.

The requirement that the physician "conduct himself with propriety in his profession and in all the actions of his life" is especially important in the case of the psychiatrist because the patient tends to model his behavior after that of his therapist by identification. Further, the necessary intensity of the therapeutic relationship may tend to activate sexual and other needs and fantasies on the part of both patient and therapist, while weakening the objectivity necessary for control. Sexual activity with a patient is unethical.

The psychiatrist should diligently guard against exploiting information furnished by the patient and should not use the unique position of power afforded him by the psychotherapeutic situation to influence the patient in any way not directly relevant to the treatment goals.

Physicians generally agree that the doctor-patient relationship is such a vital factor in effective treatment of the patient that preservation of optimal conditions for development of a sound working relationship between a doctor and his patient should take precedence over all other considerations. Professional courtesy may lead to poor psychiatric care for physicians and their families because of embarrassment over the lack of a complete give-and-take contract.

SECTION 2

Physicians should strive continually to improve medical knowledge and skill, and should make available to their patients and colleagues the benefits of their professional attainments.

Psychiatrists are responsible for their own continuing education and should be mindful of the fact that theirs must be a lifetime of learning.

SECTION 3

A physician should practice a method of healing founded on a scientific basis and he should not voluntarily associate professionally with anyone who violates this principle.

SECTION 4

The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.

It would seem self-evident that a psychiatrist who is a lawbreaker might be ethically unsuited to practice his profession. When such illegal activities bear directly upon his practice, this would obviously be the case. However, in other instances, illegal activities such as those concerning the right to protest social injustices might not bear on either the image of the psychiatrist or the ability of the specific psychiatrist to treat his patient ethically and well. While no committee or board could offer prior assurance that any illegal activity would not be considered unethical, it is conceivable that an individual could violate a law without being guilty of professionally unethical behavior. Physicians lose no right of citizenship on entry into the profession of medicine.

A psychiatrist who regularly practices outside his area of professional competence should be considered unethical. Determination of professional competence should be made by peer review boards or other appropriate bodies.

Special consideration should be given to those psychiatrists who, because of mental illness, jeopardize the welfare of their patients and their own reputations and practices. It is ethical, even encouraged, for another psychiatrist to intercede in such situations.

SECTION 5

A physician may choose whom he will serve. In an

[3] Statements in italics are taken directly from the American Medical Association's Principles of Medical Ethics or annotations thereto (1).

emergency, however, he should render service to the best of his ability. Having undertaken the care of a patient, he may not neglect him; and unless he has been discharged he may discontinue his services only after giving adequate notice. He should not solicit patients.

A psychiatrist should not be a party to any type of policy that excludes, segregates, or demeans the dignity of any patient because of ethnic origin, race, sex, creed, age, or socioeconomic status.

SECTION 6

A physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care.

Contract practice as applied to medicine means the practice of medicine under an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization, political subdivision, or individual whereby partial or full medical services are provided for a group or class of individuals on the basis of a fee schedule, for a salary, or for a fixed rate per capita.

Contract practice per se is not unethical. Contract practice is unethical if it permits features or conditions that are declared unethical in these Principles of Medical Ethics or if the contract or any of its provisions causes deterioration of the quality of the medical services rendered.

The ethical question is not the contract itself but whether or not the physician is free of unnecessary nonmedical interference. The ultimate issue is his freedom to offer good quality medical care.

In relationships between psychiatrists and practicing licensed psychologists, the physician should not delegate to the psychologist or, in fact, to any nonmedical person any matter requiring the exercise of professional medical judgment.

When the psychiatrist assumes a collaborative or supervisory role with another mental health worker, he must expend sufficient time to assure that proper care is given. It is contrary to the interests of the patient and to patient care if he allows himself to be used as a figurehead.

In the practice of his specialty, the psychiatrist consults, associates, collaborates, or integrates his work with that of many professionals, including psychologists, psychometricians, social workers, alcoholism counselors, marriage counselors, public health nurses, etc. Furthermore, the nature of modern psychiatric practice extends his contacts to such people as teachers, juvenile and adult probation officers, attorneys, welfare workers, agency volunteers, and neighborhood aides. In referring patients for treatment, counseling, or rehabilitation to any of these practitioners, the psychiatrist should ensure that the allied professional or paraprofessional with whom he is dealing is a recognized member of his own discipline and is competent to carry out the therapeutic task required. The psychiatrist should have the same attitude toward members of the medical profession to whom he refers patients. Whenever he has reason to doubt the training, skill, or ethical qualifications of the allied professional, the psychiatrist should not refer cases to him.

Also, he should neither lend the endorsement of the psychiatric specialty nor refer patients to persons, groups, or treatment programs with which he is not familiar, especially if their work is based only on dogma and authority and not on scientific validation and replication.

In accord with the requirements of law and accepted medical practice, it is ethical for a physician to submit his work to peer review and to the ultimate authority of the medical staff executive body and the hospital administration and its governing body.

SECTION 7

In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him, or under his supervision, to his patients. His fee should be commensurate with the services rendered and the patient's ability to pay. He should neither pay nor receive a commission for referral of patients. Drugs, remedies or appliances may be dispensed or supplied by the physician provided it is in the best interests of the patient.

The psychiatrist may also receive income from administration, teaching, research, education, and consultation.

Charging for a missed appointment or for one not cancelled 24 hours in advance need not, in itself, be considered unethical if a patient is fully advised that the physician will make such a charge. The practice, however, should be resorted to infrequently and always with the utmost consideration of the patient and his circumstances.[4]

Psychiatric services, like all medical services, are dispensed in the context of a contractual arrangement

[4] This paragraph is reprinted as an annotation to Section 7 in the AMA's *Opinions and Reports of the Judicial Council* (1, p. 39).

between the patient and the treating physician. The provisions of the contractual arrangement, which are binding on the physician as well as on the patient, should be explicitly established.

It is ethical for the psychiatrist to make a charge for a missed appointment when this falls within the terms of the specific contractual agreement with the patient.

SECTION 8

A physician should seek consultation upon request; in doubtful or difficult cases; or whenever it appears that the quality of the medical service may be enhanced thereby.

The psychiatrist should agree to the request of a patient for consultation or to such a request from the family of an incompetent or minor patient. The psychiatrist may suggest possible consultants, but the patient or family should be given free choice of the consultant. If the psychiatrist disapproves of the professional qualifications of the consultant or if there is a difference of opinion that the primary therapist cannot resolve he may, after suitable notice, withdraw from the case. If this disagreement occurs within an institution or agency framework, the differences should be resolved by the mediation or arbitration of higher professional authority within the institution or agency.

SECTION 9

A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community.

Psychiatric records, including even the identification of a person as a patient, must be protected with extreme care. Confidentiality is essential to psychiatric treatment. This is based in part on the special nature of psychiatric therapy as well as on the traditional ethical relationship between physician and patient. Growing concern regarding the civil rights of patients and the possible adverse effects of computerization, duplication equipment, and data banks makes the dissemination of confidential information an increasing hazard. Because of the sensitive and private nature of the information with which the psychiatrist deals, he must be circumspect in the information that he chooses to disclose to others about a patient. The welfare of the patient must be a continuing consideration.

A psychiatrist may release confidential information only with the authorization of the patient or under proper legal compulsion. The continuing duty of the psychiatrist to protect the patient includes fully apprising him of the connotations of waiving the privilege of privacy. This may become an issue when the patient is being investigated by a government agency, is applying for a position, or is involved in legal action. The same principles apply to the release of information concerning treatment to medical departments of government agencies, business organizations, labor unions, and insurance companies. Information gained in confidence about patients seen in student health services should not be released without the student's explicit permission.

Clinical and other materials used in teaching and writing must be adequately disguised in order to preserve the anonymity of the individuals involved.

The ethical responsibility of maintaining confidentiality holds equally for the consultations in which the patient may not have been present and in which the consultee was not a physician. In such instances, the physician consultant should alert the consultee to his duty of confidentiality.

Ethically the psychiatrist may disclose only that information which is immediately relevant to a given situation. He should avoid offering speculation as fact. Sensitive information such as an individual's sexual orientation or fantasy material is usually unnecessary.

Psychiatrists are often asked to examine individuals for security purposes, to determine suitability for various jobs, and to determine legal competence. The psychiatrist must fully describe the nature and purpose and lack of confidentiality of the examination to the examinee at the beginning of the examination.

Psychiatrists at times may find it necessary, in order to protect the patient or the community from imminent danger, to reveal confidential information disclosed by the patient.

Careful judgment must be exercised by the psychiatrist in order to include, when appropriate, the parents or guardian in the treatment of a minor. At the same time the psychiatrist must assure the minor proper confidentiality.

When the psychiatrist is ordered by the court to reveal the confidences entrusted to him by patients he may comply or he may ethically hold the right to dissent within the framework of the law. When the psychiatrist is in doubt, the right of the patient to confidentiality and, by extension, to unimpaired treatment, should be given priority. The psychiatrist should reserve the right to raise the question of adequate need for disclosure. In the event that the necessity for legal disclosure is demonstrated by the court, the psychiatrist may request the right to disclosure of only that information which is relevant to the legal question at hand.

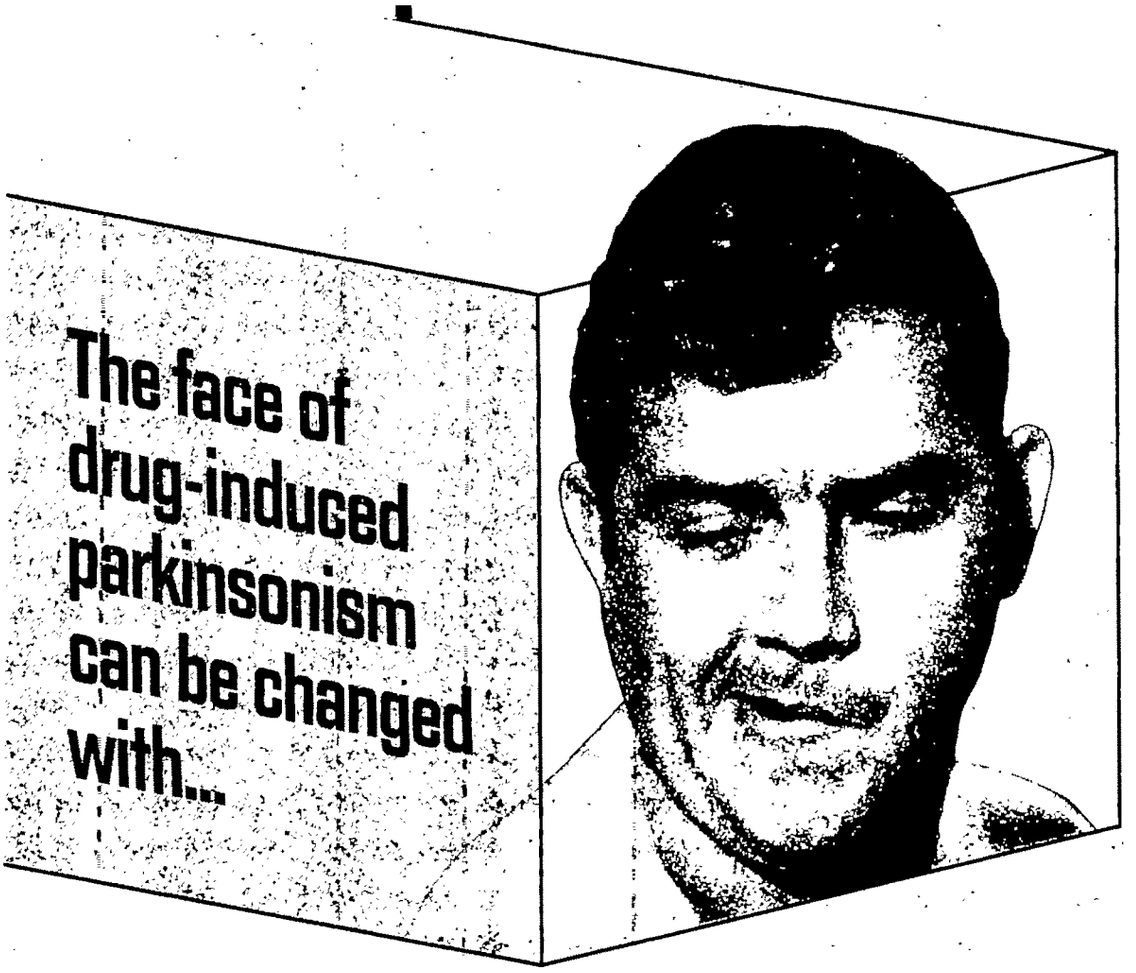
SECTION 10

The honored ideals of the medical profession im-

ply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community.

Psychiatrists should foster the cooperation of those legitimately concerned with the medical, psychological, social, and legal aspects of mental health and illness. Psychiatrists are encouraged to serve society by advising and consulting with the executive, legislative, and judiciary branches of the government. A psychiatrist should clarify whether he speaks as an individual or as a representative of an organization. Furthermore, psychiatrists should avoid clouding their public statements with the authority of the profession (e.g., "Psychiatrists know that. . .").

Psychiatrists may interpret and share with the public their expertise in the various psychosocial issues that may affect mental health and illness. Psychiatrists should always be mindful of their separate roles as dedicated citizens and as experts in psychological medicine.



On occasion psychiatrists are asked for an opinion about an individual who is in the light of public attention, or who has disclosed information about himself through public media. It is unethical for a psychiatrist to offer a diagnosis unless he has conducted an examination and has been granted proper authorization for such a statement.

The psychiatrist should not permit his certification to be used for the involuntary commitment of any person except when this is clearly necessary for the patient's own protection or the protection of others from probable injury at the patient's hands.

"A complaint concerning the behavior of a member of this Association shall be in writing, signed by the complainant, and filed with the Secretary." (Chapter 10, Section 1, By-Laws, American Psychiatric Association.)

AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally; **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

The hostile patient.

He vacillates from suspiciousness to rage.
His disorientation is apparent through
his erratic outbursts against imagined enemies.

His irrational behavior worries his family.
And hinders your treatment.
How do you reach him?

Very possibly, with QUIDE (piperacetazine).

Clinical studies of schizophrenic patients on a regimen of QUIDE have demonstrated moderate to excellent improvement in mental status and remission of hyperactive, combative behavior. Improvement in interpersonal relationships and adjustment to therapy were especially notable.

In clinical evaluation, although extrapyramidal reactions did occur, the low incidence of these reactions allowed for patient cooperation.

When Parkinsonism did occur, it was easily controlled by modification of dosage or, infrequently, the addition of an anti-Parkinson agent. Photosensitivity rarely occurred.

QUIDE (piperacetazine) . . . it may well be what some of your patients are waiting for.

Quide® tablets
piperacetazine

DOW **DOW PHARMACEUTICALS** The Dow Chemical Company Indianapolis, Indiana

See next page for complete prescribing information.

Quide® tablets
piperacetazine

DESCRIPTION: QUIDE (piperacetazine) is a piperidine derivative of phenothiazine.

Piperacetazine has the following chemical designation: 10- { 3-[4-(2-Hydroxyethyl)-piperidino]propyl } phenothiazin-2-yl Methyl Ketone.

ACTIONS: The exact mode of action of the phenothiazines is unclear, but drugs of this class produce changes at all levels of the central nervous system, as well as on multiple organ systems.

INDICATIONS: QUIDE is indicated for use in the management of the manifestations of psychotic disorders.

CONTRAINDICATIONS: QUIDE is contraindicated in patients who are comatose or markedly depressed from any cause and in the presence of preexisting thrombocytopenia and other blood dyscrasias, bone marrow depression and in patients with significant liver disease. QUIDE is contraindicated in women who are or may become pregnant since animal reproductive studies adequate to establish safety during pregnancy have not been carried out. QUIDE is contraindicated in patients who have shown hypersensitivity to the drug. Cross sensitivity between phenothiazine derivatives may occur.

WARNING: Like other phenothiazines, QUIDE may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, patients should be cautioned accordingly. Concomitant use with alcohol should be avoided due to the potential additive effect. Patients with known suicidal tendencies should not be given QUIDE except under strict medical supervision.

Use in Children: The use of QUIDE in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Use with caution in persons who:

1. are receiving barbiturates or narcotics, because of additive effects on central nervous system depression. The dosage of the narcotic or barbiturate should be reduced when given concomitantly with QUIDE.
2. are receiving atropine or related drugs, because of additive anticholinergic effects.
3. have a history of epilepsy, because this drug may lower the convulsive threshold. Adequate anticonvulsant therapy must be maintained concomitantly.
4. are exposed to extreme heat or phosphorous insecticides.
5. have a history of peptic ulcer. Aggravation of preexisting ulcer has occurred.
6. have cardiovascular disease.
7. have respiratory impairment due to acute pulmonary infections or chronic respiratory disorders such as severe asthma or emphysema.

Keep in mind that the antiemetic effect may mask the toxicity of other drugs or obscure the diagnosis of such conditions as intestinal obstruction or brain tumor.

Any sign of blood dyscrasias requires immediate discontinuance of the drug and the institution of appropriate therapy.

The possibility of liver damage, pigmentary retinopathy, lenticular or corneal deposits, and development of irreversible dyskinesias should be kept in mind when patients are on prolonged therapy.

Abrupt Withdrawal: In general, phenothiazines do not produce psychic dependence, but gastritis, nausea and vomiting, dizziness and tremulousness have been reported following abrupt cessation of high-dose therapy. Reports suggest that these symptoms can be reduced if concomitant antiparkinson agents are continued for several weeks after the phenothiazine is withdrawn.

ADVERSE REACTIONS: Not all of the following adverse reactions have been reported with QUIDE (piperacetazine), but pharmacological similarities among various phenothiazine derivatives require that each be considered.

Note: Sudden Death has occasionally been reported in patients who have received phenothiazines. In some cases death was apparently due to cardiac arrest, in others the cause appeared to be asphyxia due to failure of the cough reflex. In some patients the cause could not be determined, nor could it be established that death was due to the phenothiazine.

Drowsiness: May occur particularly during the first or second week, after which it generally disappears. If troublesome, lower the dosage.

Jaundice: Incidence is low. When it occurs (usually between the second and fourth weeks of therapy) it is generally regarded as a sensitivity reaction. The clinical picture resembles infectious hepatitis with laboratory features of obstructive jaundice. It is usually reversible although chronic jaundice has been reported with phenothiazine therapy.

Hematological Disorders: Agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenia purpura and pancytopenia.

Agranulocytosis: Most cases have occurred between the fourth and tenth weeks of therapy. Patients should be watched closely during that period for the sudden appearance of sore throat or other signs of infection. If white blood count and differential show significant cellular depression, discontinue the drug and start appropriate therapy. A slightly lowered white count, however, is not in itself an indication to discontinue the drug.

Cardiovascular: Postural hypotension, tachycardia (especially following rapid increase in dosage), bradycardia, cardiac arrest, faintness and dizziness. Occasionally the hypotensive effect may produce a shock-like condition. In the event a vasoconstrictor is required, levarterenol and phenylephrine are the most suitable. Other pressor agents, including epinephrine, should not be used because a paradoxical further lowering of the blood pressure may ensue.

EKG changes, nonspecific, usually reversible, have been observed in some patients receiving phenothiazine tranquilizers. Their relationship to myocardial damage has not been confirmed.

CNS Effects: Neuromuscular (extrapyramidal) Reactions: These are usually dose related and take three forms: (1) pseudoparkinsonism; (2) akathisia; and (3) dystonias (Dystonias include spasms of the neck muscles, extensor rigidity of back muscles, carpopedal spasm, eyes rolled back, convulsions, trismus and swallowing difficulties). These resemble serious neurological disorders but usually subside within 48 hours. Management of the extrapyramidal symptoms, depending upon the type and severity, includes sedation, injectable diphenhydramine, and the use of antiparkinsonism agents.

Hyperreflexia has been reported in the newborn when a phenothiazine was used during pregnancy.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of the mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; anti-parkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Other CNS Effects: Cerebral edema. Abnormality of cerebral spinal fluid proteins. Convulsive seizures, particularly in patients with EEG abnormalities or a history of such disorders. Hyperpyrexia.

Adverse Behavioral Effects: Paradoxical exacerbation of psychotic symptoms.

Allergic Reactions: Urticaria, itching, erythema, photosensitivity (avoid undue exposure to the sun) eczema. Severe reactions include: exfoliative dermatitis (rare); contact dermatitis in nursing personnel administering the drug; asthma; laryngeal edema; angioneurotic edema; and anaphylactoid reactions.

Endocrine Disorders: Lactation and moderate breast engorgement in females and gynecomastia in males on large doses; changes in libido; false-positive pregnancy tests; amenorrhea; hyperglycemia, hypoglycemia, glycosuria.

Autonomic Reactions: Dry mouth, nasal congestion, constipation, adynamic ileus, myosis, mydriasis, urinary retention.

Special Considerations in Long-term Therapy: After prolonged administration of phenothiazines, pigmentation of the skin has occurred chiefly in the exposed areas, especially in females on large doses. Ocular changes consisting of deposition of fine particulate matter in the cornea and lens, progressing in more severe cases to star-shaped lenticular opacities; epithelial keratopathies; pigmentary retinopathy.

Other Adverse Reactions: Increases in appetite and weight; peripheral edema.

DOSAGE AND ADMINISTRATION: Dosage should be individualized, not only initially but during the course of therapy, and the minimal effective dose should always be employed. A starting dosage of 10 mg. two to four times daily is recommended for adults. The dose may be increased up to 160 mg. daily within a three to five day period. Should side effects occur, dosage should be reduced or discontinued as indicated. For maintenance therapy, up to 160 mg. daily in divided doses may be given.

OVERDOSAGE WITH PHENOTHIAZINES:
Manifestations: One of three clinical pictures may be seen.

1. Extreme somnolence; patient can usually be roused with prodding, but if permitted will fall asleep. General condition is usually satisfactory. The skin, though pale, is warm and dry. Slight blood pressure, respiratory and pulse changes may occur but are not problems.
2. Mild to moderate drop in blood pressure (patient may be conscious or unconscious). Skin is markedly gray but warm and dry. Nail beds are pink. Respiration is slow and regular. Pulse is strong but rate slightly increased.
3. Severe hypotension, possibly accompanied by weakness, cyanosis, perspiration, rapid thready pulse and respiratory depression.

Treatment: Is essentially symptomatic and supportive. Early gastric lavage and intestinal purges may help. Centrally acting emetics may not help because of the possible antiemetic effect of QUIDE. Give hot tea or coffee. Severe hypotension usually responds to measures described under hypotensive effects (see ADVERSE REACTIONS: *Cardiovascular).* Additional measures include pressure bandages to lower limbs, oxygen and I.V. fluids.

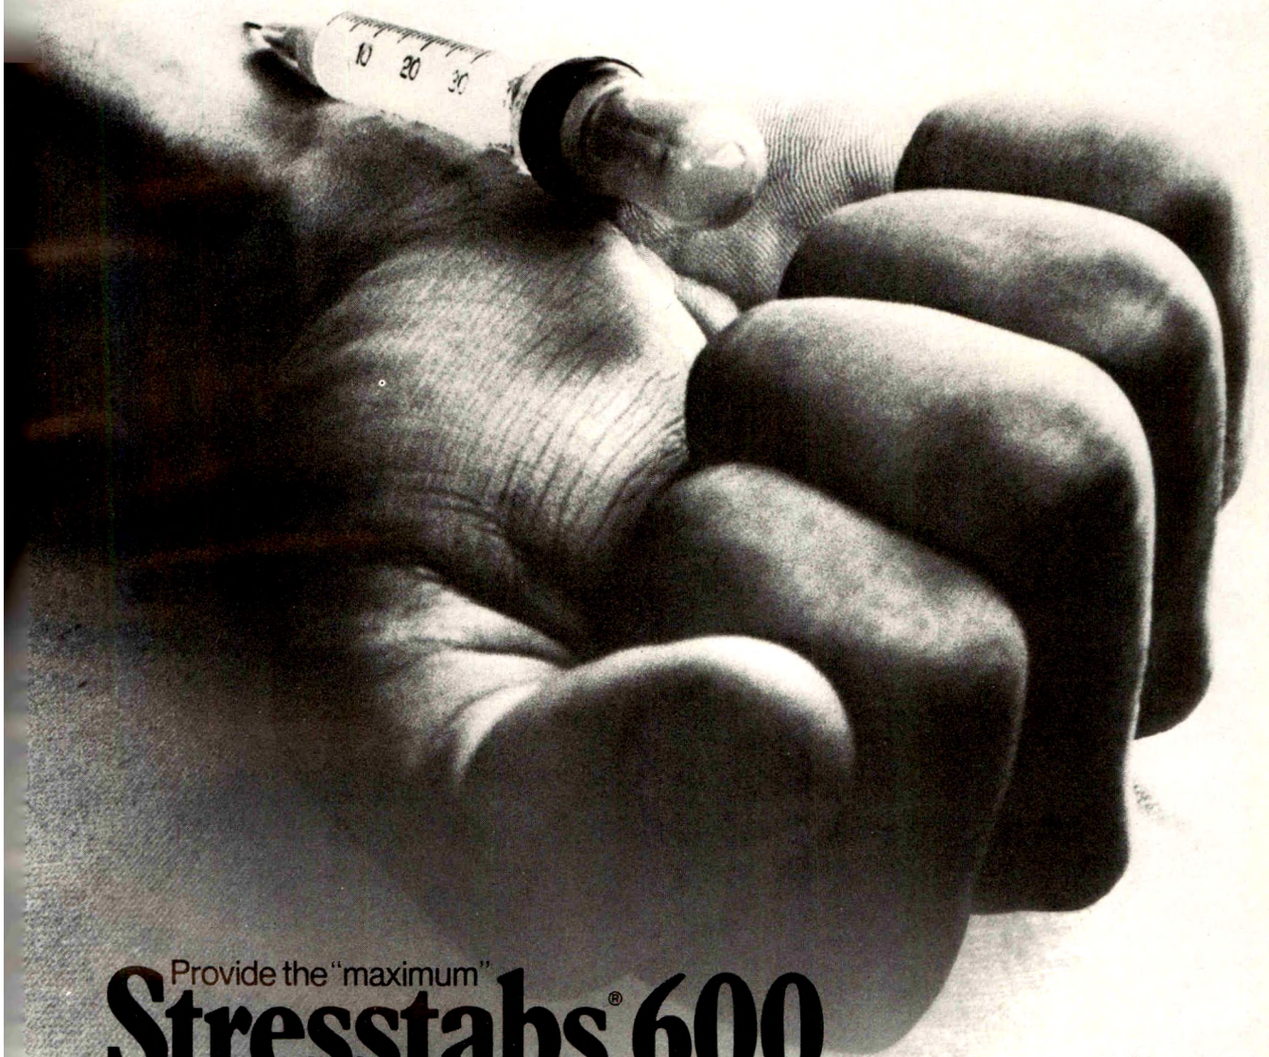
Avoid stimulants that may cause convulsions (e.g., picrotoxin and pentylenetetrazol).

Limited experience with dialysis indicates that it is not helpful.

CAUTION: Federal law prohibits dispensing without prescription.

HOW SUPPLIED:

QUIDE (piperacetazine) Tablets—10 mg. (orange)–bottles of 100 (NDC 183-52-2), and bottles of 1000 (NDC 183-52-4).



QUIDE (piperacetazine) Tablets—25 mg. (yellow)–bottles of 100 (NDC 183-53-2), and bottles of 1000 (NDC 183-53-4).

Note: Dispense only in light-resistant containers; the coatings on these tablets contain light-sensitive colors.

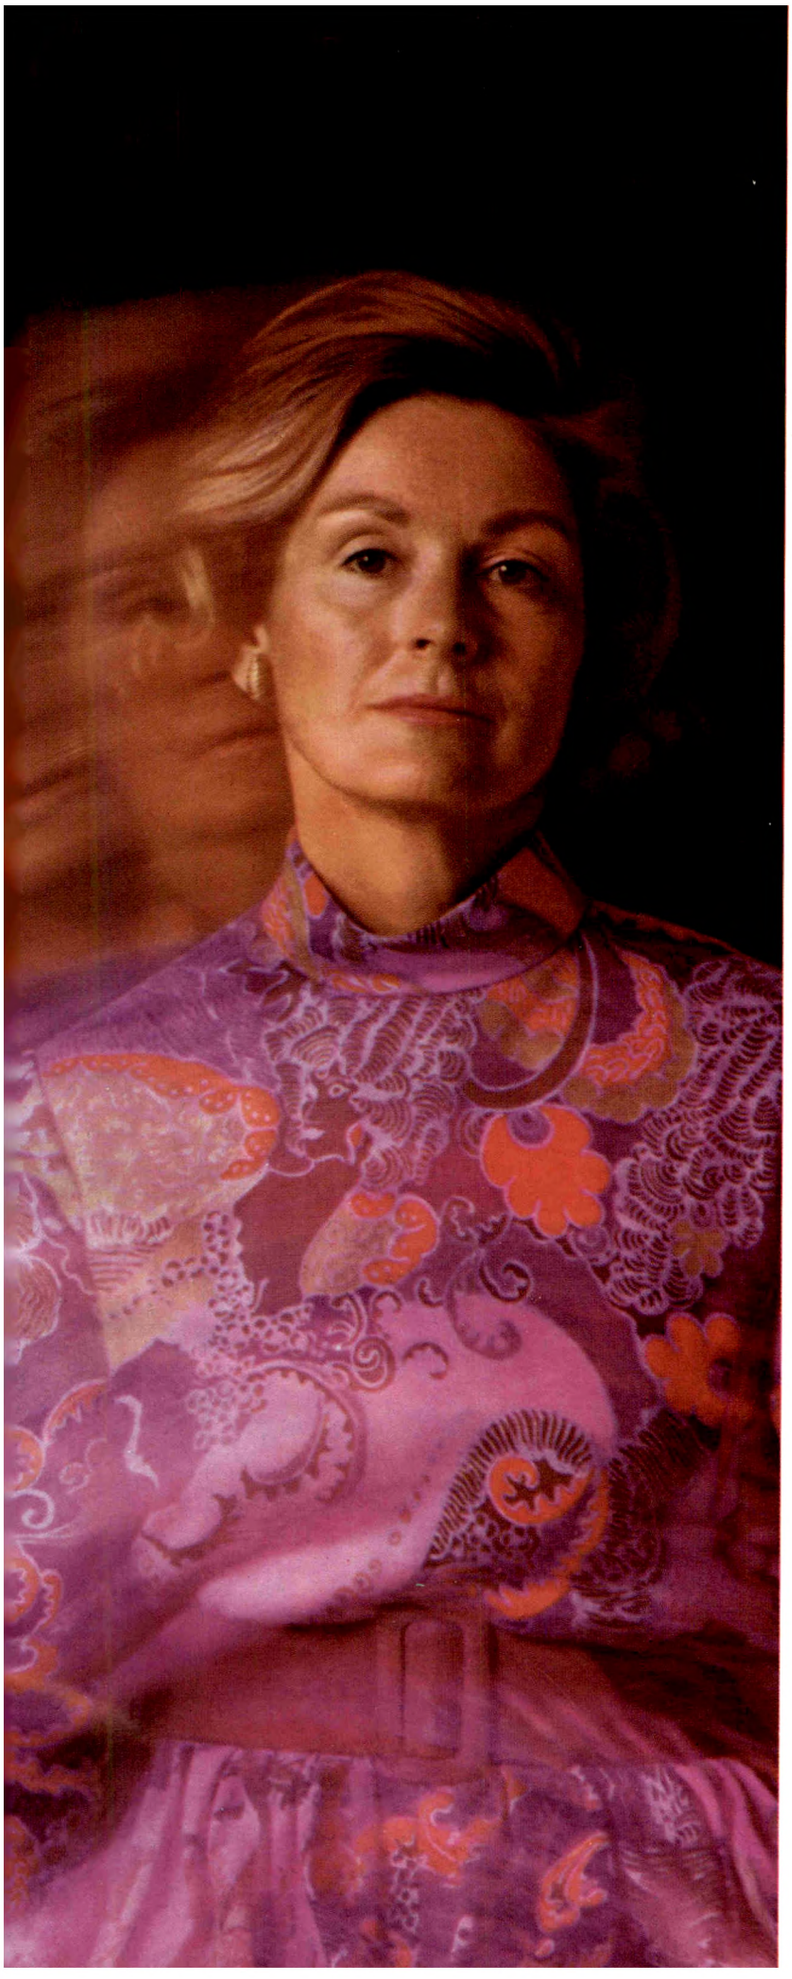
High Potency Stress Formula Vitamins



Each Tablet Contains:

Vitamin B_1 (as Thiamine Mononitrate)	15 mg (15 MDR)
Vitamin B_2 (Riboflavin)	15 mg (12½ MDR)
Vitamin B_6 (Pyridoxine Hydrochloride)	5 mg
Vitamin B_{12} (as present in concentrated extractives from streptomyces fermentation)	5 mcgm
Vitamin C (as Sodium Ascorbate and Niacinamide Ascorbate)	600 mg (20 MDR)
Niacinamide (as Niacinamide Ascorbate)	100 mg (10 MDR)
Vitamin E (as *d*-Alpha Tocopheryl Acid Succinate)	30 Units
Calcium Pantothenate USP	20 mg

MDR—Adult Minimum Daily Requirement. Recommended Intake: Adults, 1 tablet daily or as directed by physician. Supplied: Bottles of 60 and 500.

Lederle LEDERLE LABORATORIES, Division of American Cyanamid Company, Pearl River, New York 10965 732-3

Focus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS

Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

This man will self-destruct...

ALCOHOLISM

shortens the abuser's life-span by 10 to 12 years*

Private problem/ Public menace

Besides having a shortened life expectancy, the alcoholic is roughly twice as likely to develop hypertension, ulcers, or cerebrovascular disease; 29 times as likely to develop cirrhosis of the liver; and 58 times as apt to commit suicide as the non-alcoholic. Moreover, an estimated 28,000 automobile deaths each year involve drinking drivers, and alcohol addiction, directly or indirectly, causes almost half of all the crimes in this country.

ANTABUSE® (disulfiram) when he's ready for help

For almost 25 years, ANTABUSE has proved its effectiveness as a medical adjunct in the management of alcoholics who are motivated to recover. ANTABUSE offers strong deterrent action to help them maintain sobriety and participate in a total treatment program, including supportive measures such as psychotherapy and/or concerned people, agencies, or organizations (e.g., Alcoholics Anonymous).

When you prescribe ANTABUSE and the alcoholic patient accepts it, he strengthens his resolve to stop drinking with each daily tablet he takes. If he drinks while the ANTABUSE effect remains in his bloodstream, he will become intensely ill. **The patient must be given a clear and detailed account of the effects of ingesting even a small amount of alcohol after he has taken ANTABUSE, and must be told that such effects may occur even up to 14 days after the last dose.** This factor deters impulsive drinking, shores up the patient's resolve, and helps enforce his sobriety. And, since ANTABUSE is nonhabituating, there's no chance of cross-addiction...a decided advantage in helping the motivated alcoholic stay on a long-term rehabilitation program.

*According to the National Institute on Alcohol Abuse and Alcoholism, alcohol abusers are estimated to shorten their life-span by an average of 10 to 12 years.

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE® (disulfiram) In Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

ANTABUSE®
Brand of DISULFIRAM

A strong deterrent for the alcoholic who doesn't want to drink

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

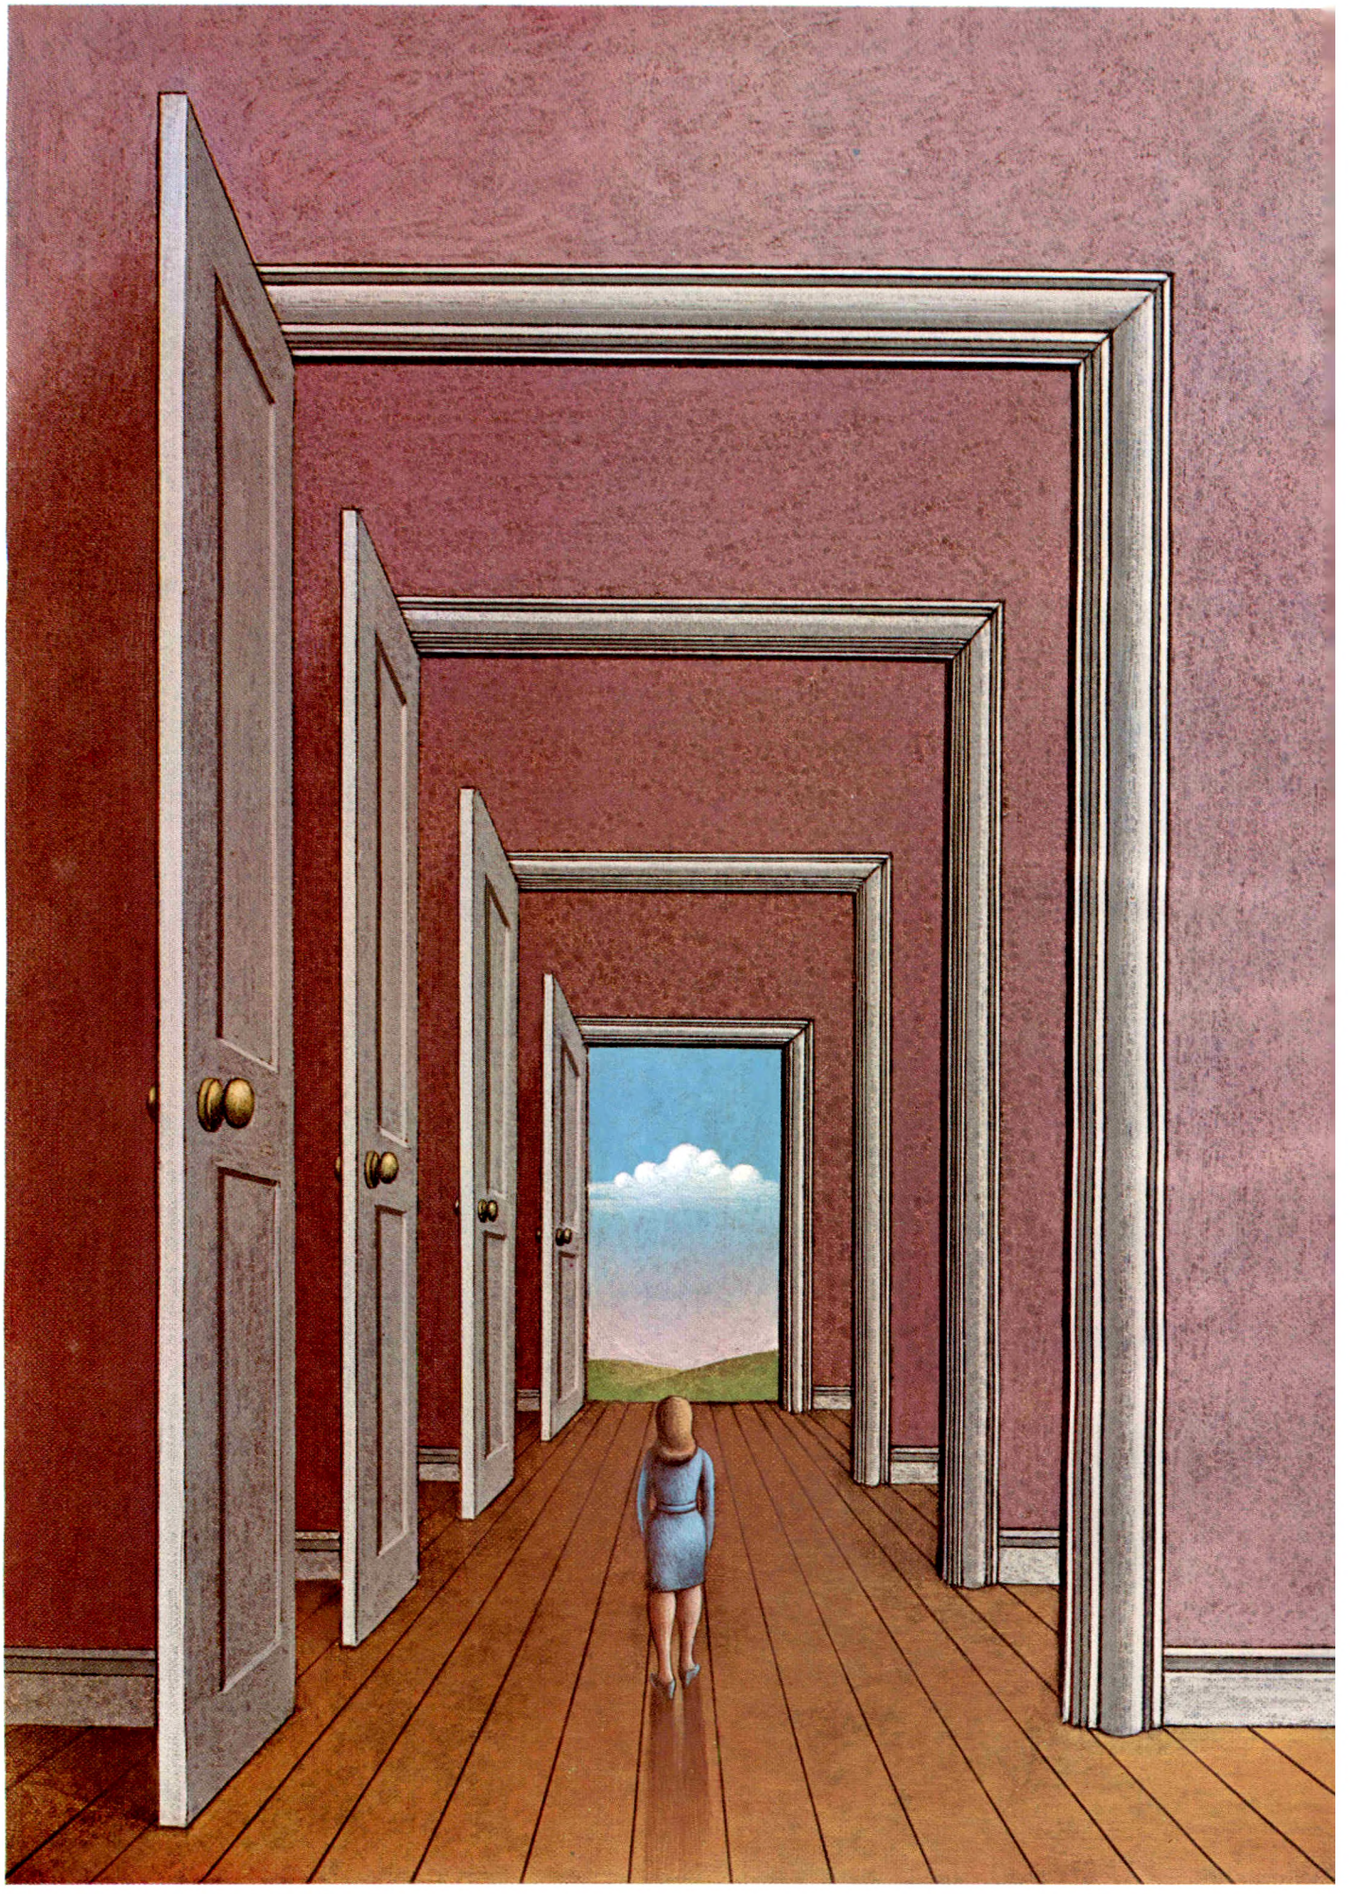
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.



HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

Alcoholism/ANTABUSE® (disulfiram)

Ayerst®

AYERST LABORATORIES
New York, N.Y. 10017

7343

A HEAD START FOR THE CLINICALLY DEPRESSED PATIENT.

All tricyclic antidepressants take from one to four weeks before optimal antidepressant effect is seen.

Sinequan (doxepin HCl)—the newest tricyclic antidepressant—is no exception.

But, in that waiting period, Sinequan offers the clinically depressed patient both:

prompt sedative activity to begin relieving the sleep disturbances often characteristic of depression, and

marked antianxiety activity to help relieve the apprehension, tension, worry and fear that usually accompany depression.

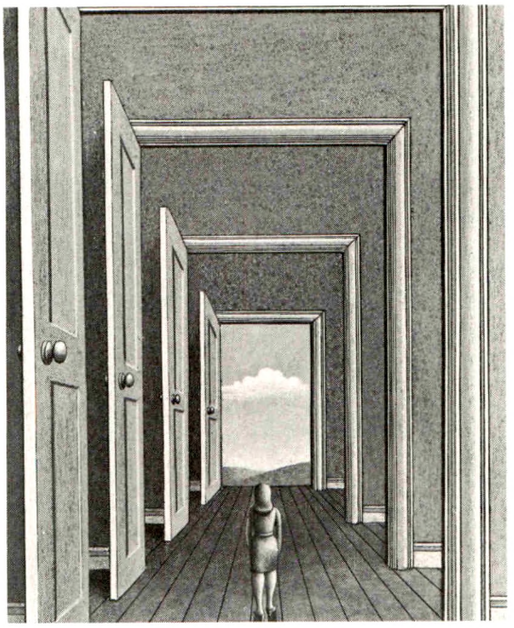
Further, the incidence of cardiovascular side effects with Sinequan is relatively low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) And Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses.

Prompt sedative activity. Marked antianxiety activity. Low incidence of cardiovascular side effects.

It's a head start for the clinically depressed patient.

THE NEWEST TRICYCLIC ANTIDEPRESSANT— WITH DIFFERENCES YOU CAN SEE.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules



Pfizer **LABORATORIES DIVISION**
PFIZER INC.

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

©1973, PFIZER INC.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules

THE NEWEST TRICYCLIC ANTIDEPRESSANT–WITH DIFFERENCES YOU CAN SEE.

BRIEF SUMMARY
Sinequan® (doxepin HCl) **Capsules**
Contraindications. Sinequan (doxepin HCl) is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan (doxepin HCl) is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan (doxepin HCl) has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan (doxepin HCl) in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan (doxepin HCl). The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan (doxepin HCl) has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan (doxepin HCl), however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan (doxepin HCl) can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan (doxepin HCl) does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) was similar to the other structurally related psychotherapeutic agents as regards its ability to potentiate norepinephrine response in the animal. However, in the human this effect was not seen. This is in agreement with the low incidence of the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and constipation have been reported. They are usually mild, and often subside with continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usually occurs early in the course of treatment, and tends to disappear as therapy is continued.

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as increased sweating, weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan (doxepin HCl) is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., and 50 mg. of doxepin in bottles of 100 and 1000.

More detailed professional information available on request.

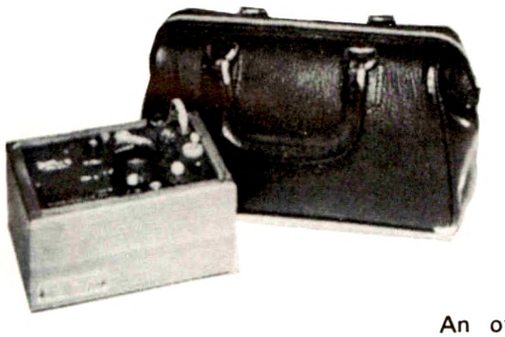
Pfizer **LABORATORIES DIVISION**
PFIZER INC.

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



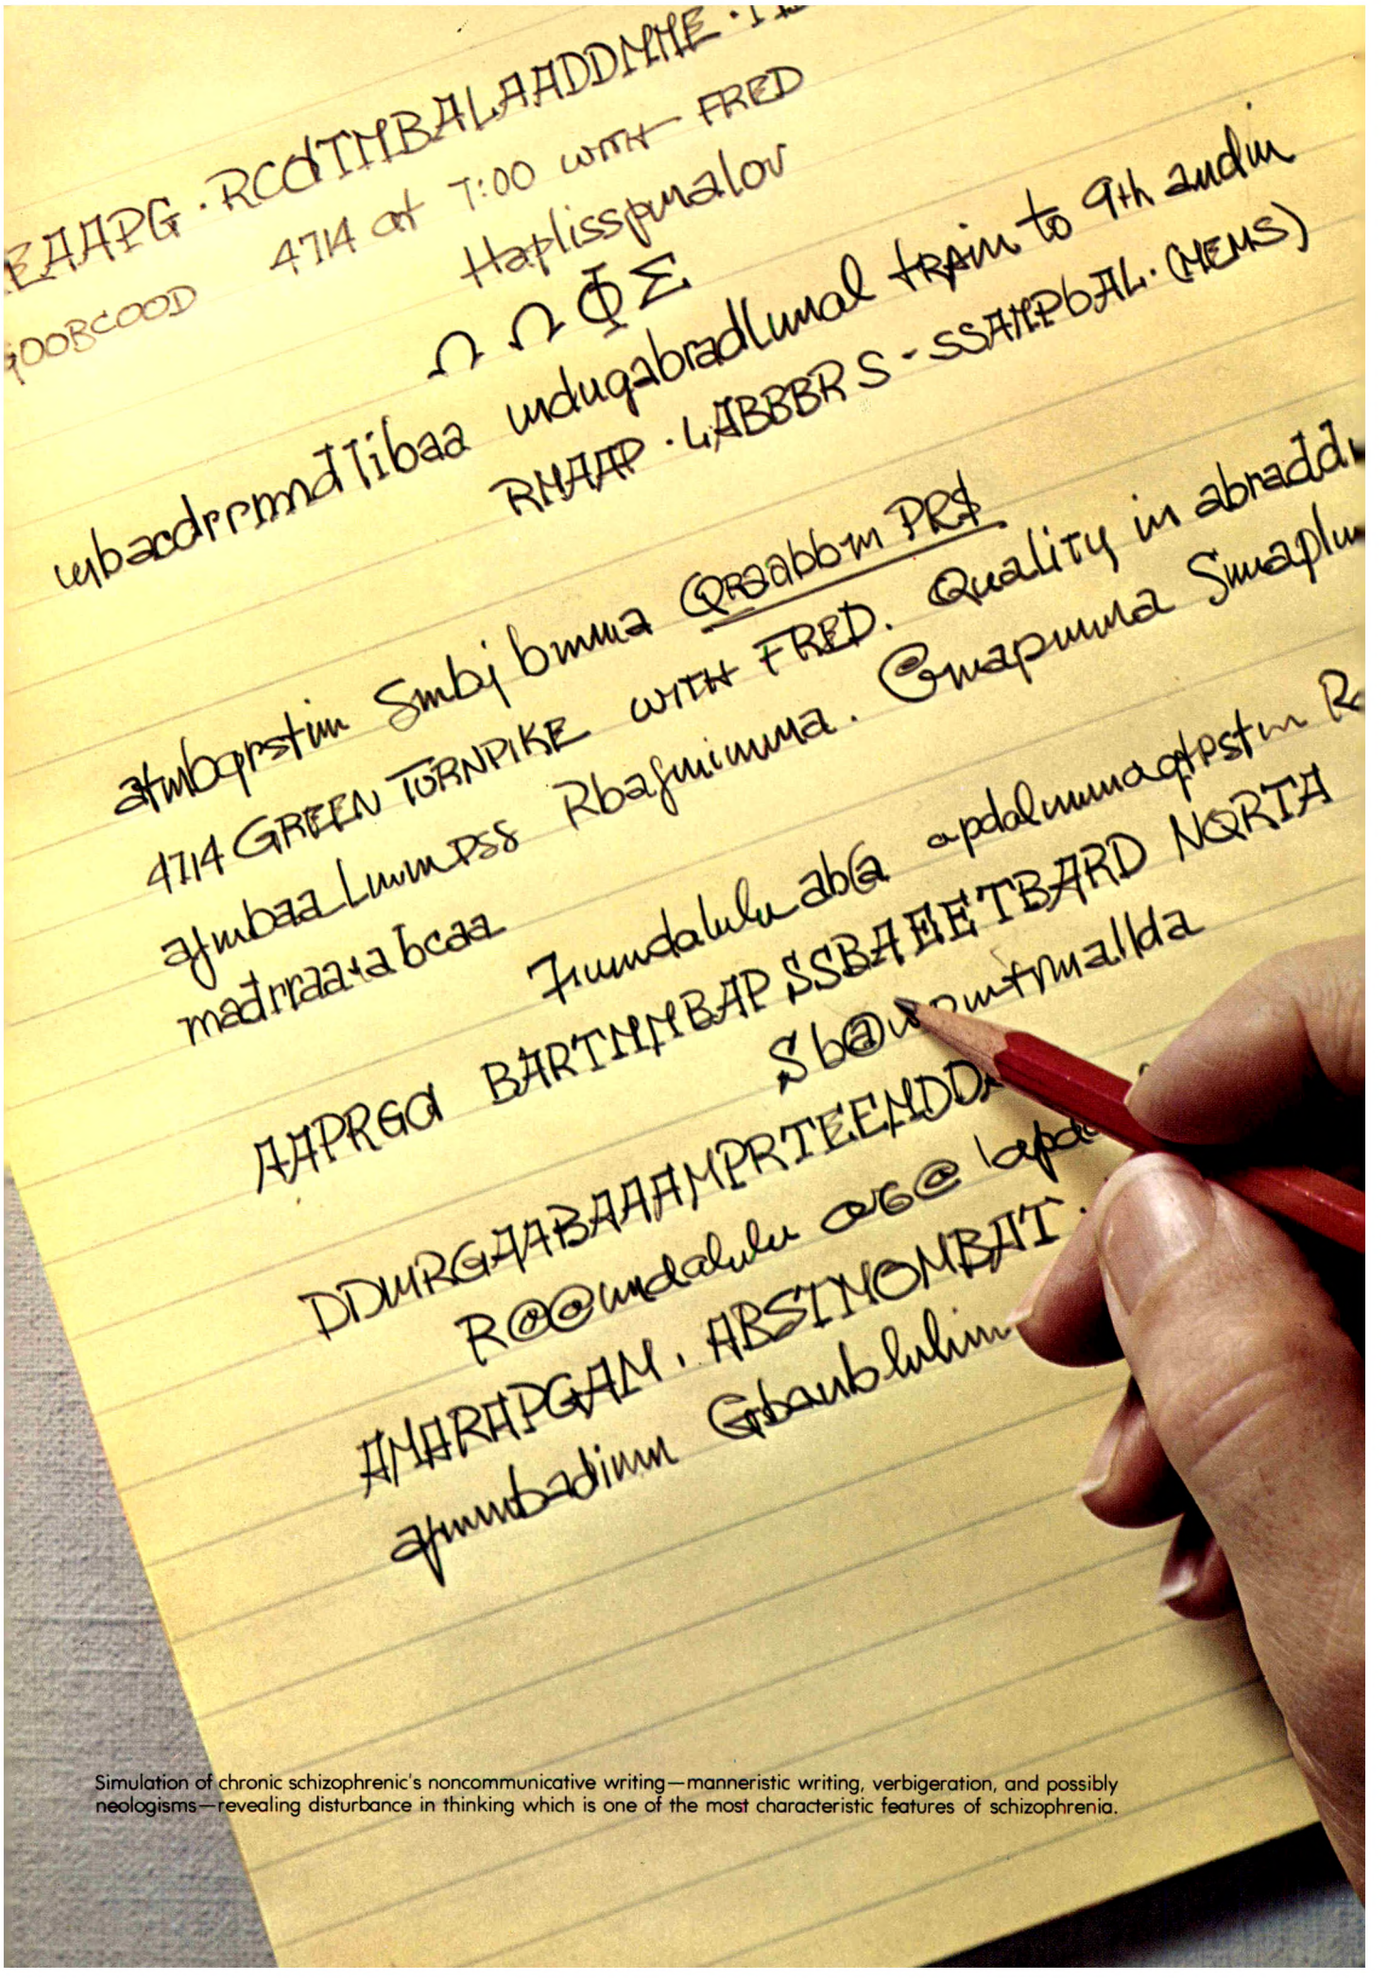
The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

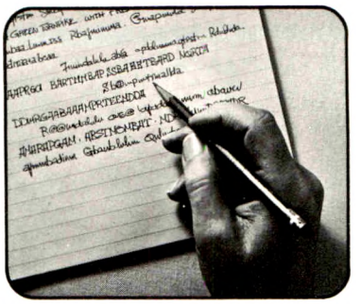
SPECIAL MODEL SOS available without unidirectional convulsive current.



The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

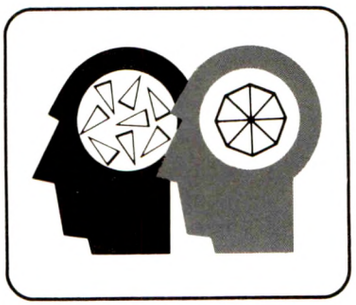
Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.



For more detailed information, and bibliography of over 200 references, write to:

REUBEN REITER, Sc.D., INC. 187 Sylvan Ave., Leonia, N.J. 07605 — Tel. (201) 944-1211

Simulation of chronic schizophrenic's noncommunicative writing—manneristic writing, verbigeration, and possibly neologisms—revealing disturbance in thinking which is one of the most characteristic features of schizophrenia.



Jnusual thought content...
a target symptom
in schizophrenia
that responds
particularly well
to treatment
with SERENTIL®
(mesoridazine)
Tablets, 50 mg. (as the besylate)
The disturbances in thinking and conceptualization that are most characteristic of schizophrenia are particularly responsive to treatment with Serentil. Symptoms of unusual thought content, conceptual disorganization, and hallucinatory behavior—whatever their degree of severity—are potentially reversible.
Serentil is effective in both acute and chronic forms of schizophrenia. Serentil Tablets and Concentrate provide dosage flexibility for initiating and maintaining therapy for both hospitalized and discharged patients.
The injectable form of Serentil is especially valuable for efficient management of symptoms in many newly admitted patients and for rapid control of acute episodes in office practice.
For brief summary, please see following page.
SANDOZ
73-731

Unusual thought content...

a target symptom in schizophrenia that responds particularly well to treatment with

SERENTIL®
(mesoridazine)
Tablets, 50 mg. (as the besylate)

Contraindications: Severe central nervous system depression; comatose states from any cause; hypersensitivity.

Warnings: Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides.

Usage in Pregnancy: Safe use in pregnancy has not been established; administer only when the potential benefits exceed the possible risks to mother and fetus.

Usage in Children: Not recommended in children under 12 years.

Precautions: Although ocular changes to date have not been related to mesoridazine, such changes have been seen with other drugs of this class. Because of possible hypotensive effects, reserve parenteral administration for bedfast patients or for acute ambulatory cases, and keep patient lying down for at least ½ hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy; a single case of transient granulocytopenia has been associated with Serentil. Since convulsive seizures have been reported, patients receiving anticonvulsant medication should be maintained on that regimen while receiving Serentil.

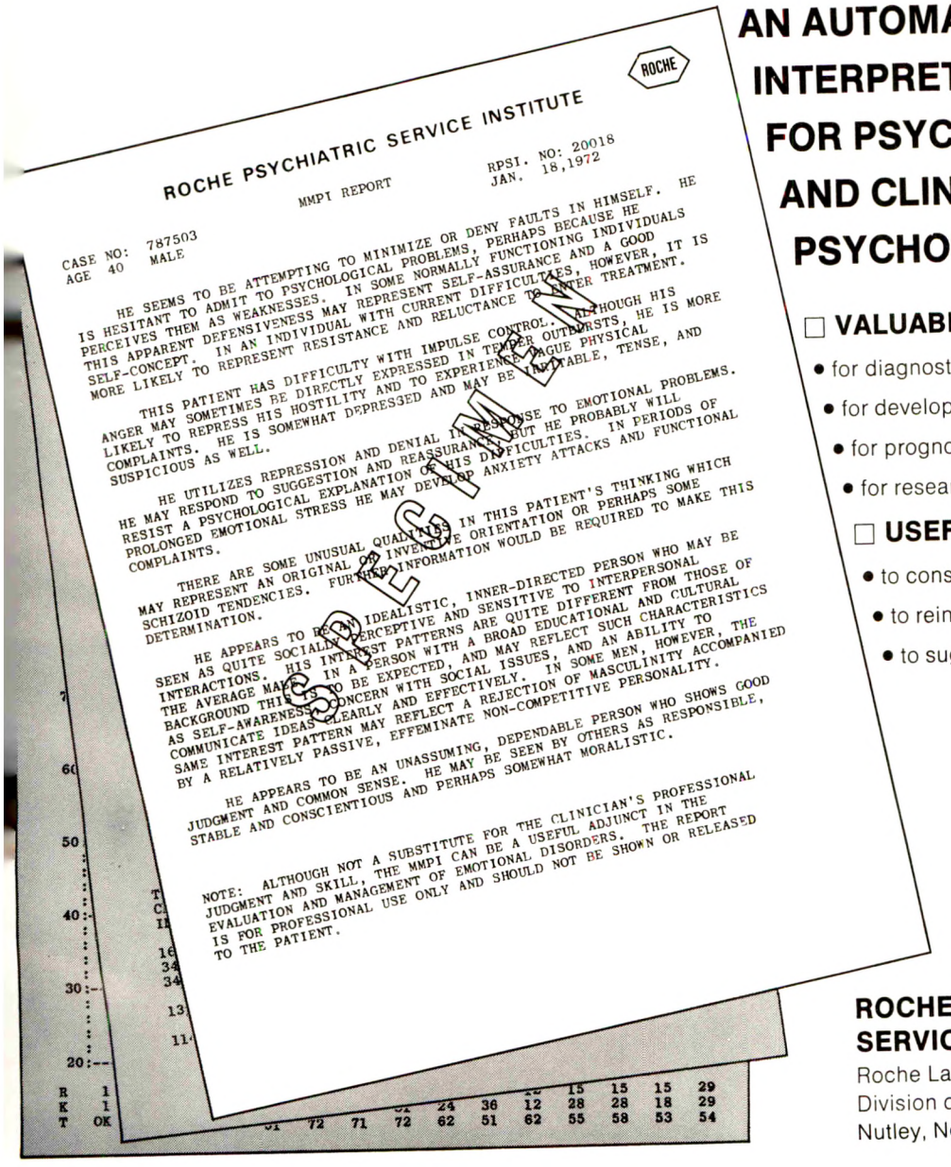
Adverse Reactions: Drowsiness and hypotension are the most prevalent side effects encountered. Side effects tend to reach their maximum level of severity early with the exception of a few (rigidity and motoric effects) which occur later in therapy. With the exceptions of tremor and rigidity, adverse reactions were generally found among patients who received relatively high doses early in treatment.

Central Nervous System: Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). *Autonomic Nervous System:* Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision. *Genitourinary System:* Inhibition of ejaculation, impotence, enuresis, incontinence. *Skin:* Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. *Cardiovascular System:* Hypotension and tachycardia; EKG changes (see *Cardiovascular Effects* below).

The following have occurred with phenothiazines and should be considered: *Autonomic Reactions:* Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions:* Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias:* Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions:* Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity:* Jaundice, biliary stasis. *Cardiovascular Effects:* Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Serentil (mesoridazine); these appear to be reversible and due to altered re arization, not myocardial damage. While the no evidence of a causal relationship bet these changes and significant disturbanc cardiac rhythm, sudden and unexpected de apparently due to cardiac arrest have occu in patients showing characteristic electroca graphic changes while taking the drug. V proposed, periodic electrocardiograms are regarded as predictive. Hypotension, rarel sulting in cardiac arrest. *Extrapyramidal S toms:* Akathisia, agitation, motor restless dystonic reactions, trismus, torticollis, opi tonus, oculogyric crises, tremor, muscular rig akinesia. *Persistent Tardive Dyskinesia:* Persi and sometimes irreversible tardive dyskin characterized by rhythmical involuntary m ments of the tongue, face, mouth, or jaw (protrusion of tongue, puffing of cheeks, pu ing of mouth, chewing movements) and s times of extremities may occur on long- therapy or after discontinuation of therapy, the risk being great elderly patients on high-dose therapy, especially females; if symptom pear, discontinue all antipsychotic agents. Syndrome may be mask treatment is reinstituted, dosage is increased, or antipsychotic a is switched. Fine vermicular movements of tongue may be an e sign, and syndrome may not develop if medication is stopped at time. *Endocrine Disturbances:* Menstrual irregularities, altered lib gynecomastia, lactation, weight gain, edema, false positive p nancy tests. *Urinary Disturbances:* Retention, incontinence. Ot Hyperpyrexia; behavioral effects suggestive of a paradoxical reac including excitement, bizarre dreams, aggravation of psychoses, toxic confusional states; following long-term treatment, a pec skin-eye syndrome marked by progressive pigmentation of ski conjunctiva and/or accompanied by discoloration of exposed s and cornea; stellate or irregular opacities of anterior lens and cor

How Supplied: *Tablets:* 10 mg., 25 mg., 50 mg., and 100 mesoridazine (as the besylate). Packages of 100 and 5000.

Ampuls: 1 cc. [25 mg. mesoridazine (as the besylate)]. Ina ingredients—Disodium Edetate, U.S.P., 0.5 mg.; Sodium Chlo U.S.P., 7.2 mg.; Carbon Dioxide Gas (Bone Dry) q.s., Water fo jection, U.S.P., q.s. to 1 cc. Boxes of 20 and 100.



Concentrate: contains 25 mg. mesoridazine (as the besylate) pe Immediate containers: Amber glass bottles of 4 fl. oz. (118 packaged in cartons of 12 bottles, with an accompanying dro graduated to deliver 10 mg., 25 mg., and 50 mg. of mesorido (as the besylate). Store below 77° F; protect from light; disp in amber glass bottles only. May be diluted with distilled w acidified tap water, orange juice or grape juice just prior to adr tration; preparation and storage of bulk dilutions is not recommer

Before prescribing or administering, see package insert or PDR.

Minnesota Multiphasic Personality Inventory

ROCHE PSYCHIATRIC SERVICE INSTITUTE

MMPI REPORT

RPSI. NO: 20018
JAN. 18,1972

CASE NO: 787503
AGE 40 MALE

HE SEEMS TO BE ATTEMPTING TO MINIMIZE OR DENY FAULTS IN HIMSELF. HE IS HESITANT TO ADMIT TO PSYCHOLOGICAL PROBLEMS, PERHAPS BECAUSE HE PERCEIVES THEM AS WEAKNESSES. IN SOME NORMALLY FUNCTIONING INDIVIDUALS THIS APPARENT DEFENSIVENESS MAY REPRESENT SELF-ASSURANCE AND A GOOD SELF-CONCEPT. IN AN INDIVIDUAL WITH CURRENT DIFFICULTIES, HOWEVER, IT IS MORE LIKELY TO REPRESENT RESISTANCE AND RELUCTANCE TO ENTER TREATMENT.

THIS PATIENT HAS DIFFICULTY WITH IMPULSE CONTROL. ALTHOUGH HIS ANGER MAY SOMETIMES BE DIRECTLY EXPRESSED IN TEMPER OUTBURSTS, HE IS MORE LIKELY TO REPRESS HIS HOSTILITY AND TO EXPERIENCE VAGUE PHYSICAL COMPLAINTS. HE IS SOMEWHAT DEPRESSED AND MAY BE IRRITABLE, TENSE, AND SUSPICIOUS AS WELL.

HE UTILIZES REPRESSION AND DENIAL IN RESPONSE TO EMOTIONAL PROBLEMS. HE MAY RESPOND TO SUGGESTION AND REASSURANCE, BUT HE PROBABLY WILL RESIST A PSYCHOLOGICAL EXPLANATION OF HIS DIFFICULTIES. IN PERIODS OF PROLONGED EMOTIONAL STRESS HE MAY DEVELOP ANXIETY ATTACKS AND FUNCTIONAL COMPLAINTS.

THERE ARE SOME UNUSUAL QUALITIES IN THIS PATIENT'S THINKING WHICH MAY REPRESENT AN ORIGINAL OR INVENTIVE ORIENTATION OR PERHAPS SOME SCHIZOID TENDENCIES. FURTHER INFORMATION WOULD BE REQUIRED TO MAKE THIS DETERMINATION.

HE APPEARS TO BE AN IDEALISTIC, INNER-DIRECTED PERSON WHO MAY BE SEEN AS QUITE SOCIALLY PERCEPTIVE AND SENSITIVE TO INTERPERSONAL INTERACTIONS. HIS INTEREST PATTERNS ARE QUITE DIFFERENT FROM THOSE OF THE AVERAGE MALE. IN A PERSON WITH A BROAD EDUCATIONAL AND CULTURAL BACKGROUND THIS IS TO BE EXPECTED, AND MAY REFLECT SUCH CHARACTERISTICS AS SELF-AWARENESS, CONCERN WITH SOCIAL ISSUES, AND AN ABILITY TO COMMUNICATE IDEAS CLEARLY AND EFFECTIVELY. IN SOME MEN, HOWEVER, THE SAME INTEREST PATTERN MAY REFLECT A REJECTION OF MASCULINITY ACCOMPANIED BY A RELATIVELY PASSIVE, EFFEMINATE NON-COMPETITIVE PERSONALITY.

HE APPEARS TO BE AN UNASSUMING, DEPENDABLE PERSON WHO SHOWS GOOD JUDGMENT AND COMMON SENSE. HE MAY BE SEEN BY OTHERS AS RESPONSIBLE, STABLE AND CONSCIENTIOUS AND PERHAPS SOMEWHAT MORALISTIC.

NOTE: ALTHOUGH NOT A SUBSTITUTE FOR THE CLINICIAN'S PROFESSIONAL JUDGMENT AND SKILL, THE MMPI CAN BE A USEFUL ADJUNCT IN THE EVALUATION AND MANAGEMENT OF EMOTIONAL DISORDERS. THE REPORT IS FOR PROFESSIONAL USE ONLY AND SHOULD NOT BE SHOWN OR RELEASED TO THE PATIENT.

The challenge: versatility

The stereotype image of "psychiatrist and couch" is a anachronism because today's psychiatrist is called on to diag nose and treat depression in a variety of clinical settings. An when an antidepressant medication is chosen, it must be as flexible and as adaptable as the physician prescribing it.

The psychiatrist's office still represen the setting in which the psychoanalyt process recognizes its fullest potentia Frequently, however, an antidepressan must be employed to foster a working the apeutic relationship. With effective symp tomatic relief often provided by ELAVI (Amitriptyline HCl, MSD), depressed pa tients may be able to concentrate on underlying factors instea of somatic manifestations.

The general hospital today usually provides a psychiatri unit where depressed patients are treated. Here, too, th symptomatic relief ELAVIL often provides can be a valuable part of total treatment. As depressive symptoms are relieved, for example, patients may take advantage of the therapeutic activities offered and, even more important, may be discharged sooner and treated on an outpatient basis.

n the outpatient clinic, where follow-p treatment may be necessary for three nonths or longer, ELAVIL is highly ef-ective in maintaining relief, especially n patients who responded well to higher oses while hospitalized. As a result, nese patients may continue to function n their daily activities.

n the mental hospital, severely depressed patients present hallenges for psychiatrist and staff alike. Here, the useful-ess of ELAVIL is increased by the 50-mg tablet that provides the higher doses often required and by the injectable form for more rapid effect.

The community mental health center, a remarkable innovation in the field of modern psychiatry, offers a unique setting for treating patients with clinically significant depression. Here, too, ELAVIL often proves to be a true asset to the psychiatrist by providing highly effective symptomatic relief that can encourage communication, support the psychotherapeutic relationship, and accelerate the achievement of desired therapeutic goals.

in the treatment of depression

TABLETS: 10 mg, 25 mg, and 50 mg INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

helps open many doors

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

dosage forms for differing patient needs

25 mg (yellow)

This tablet may prove useful for most outpatients, who generally do well on 25 mg three times a day. This dosage may be increased to a total of 150 mg a day. Dosage increases are made preferably in the late afternoon or at bedtime. The sedative effect may be apparent before the antidepressant effect is noted. An adequate therapeutic effect may take as long as 30 days to develop.

50 mg (beige)

The 50-mg tablet may be indicated whenever higher dosages are required, as for example when increases are necessary in the late afternoon or bedtime doses. It may also be convenient for many hospitalized patients who may need 100 mg a day initially. In these patients, dosage may be increased gradually to 200 mg a day if necessary. A small number of hospitalized patients may need as much as 300 mg a day.

10 mg (blue)

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher dosages.

INJECTION
10 mg per ml

For patients unable or unwilling to take tablets, the injectable form may be suitable initially. The tablets should replace the injection as soon as possible. Initial intramuscular dosage is 20 to 30 mg (2 to 3 ml) four times a day. When Injection ELAVIL is administered intramuscularly, the effects may appear more rapidly than with oral administration.

Usage in Children: In view of the lack of experience in children, this drug is not recommended at the present time for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.
When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics,close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: The intravenous administration of 1-3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

helps open many doors

Suspicious and hostile?...Or accessible?

While psychotic symptoms remain acute, the barrier between you and the overly suspicious, hostile patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

accessibility often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

© McNeil Laboratories, Inc., 1973

Haldol®
(HALOPERIDOL)
a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate
for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: HALDOL (haloperidol) is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 6/73

an inexpensive way to "write"
chlorpromazine

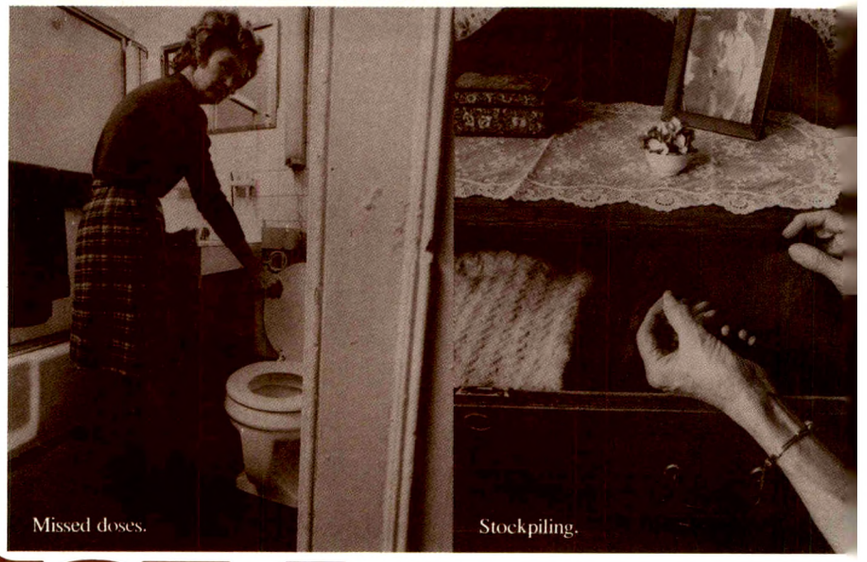
CHLOR-PZ™

BRAND OF

CHLORPROMAZINE HCl

The cost of chlorpromazine has been reduced. Introducing CHLOR-PZ, a quality chlorpromazine at a lower price. You can prescribe CHLOR-PZ in a wide variety of strengths for your patients. And who knows...maybe they'll be just a little less disturbed knowing their prescription costs less.

CHLOR-PZ.
It lowers the price of long-term therapy.



USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

BEFORE PRESCRIBING, CONSULT PACKAGE INSERT FOR COMPLETE PRODUCT INFORMATION.

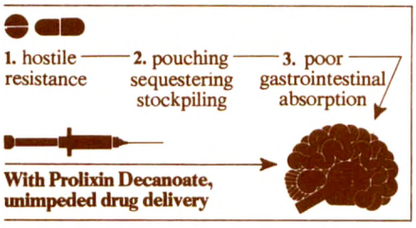
PHARMACEUTICALS

FOUR REASONS FOR READMISSION...



For schizophrenic patients...

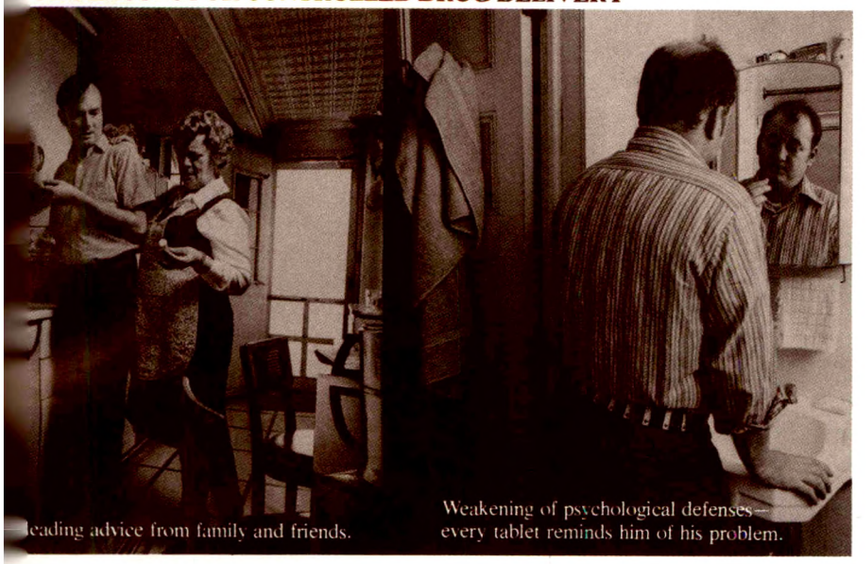
A way out

that helps them stay out

Controlled Drug Delivery with
PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)
Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer, with an average duration of effect of about 2 weeks

Controlled drug delivery helps prevent disruption of therapy—one of the commonest causes of psychotic relapse. For the inpatient it means unimpeded drug delivery with improved chances of discharge.

For the outpatient it means improve chances for prolonged remission: "...th duration of remission and the incidenc of relapse are directly related to keepin the patient medicated after his return t the community."[1]



Controlled drug delivery helps the inpatient out

- Keeps the patient medicated...help make him more manageable, more co fortable, and more amenable to tota treatment. With oral medication, on th other hand, approximately one out c every five patients does not take his me ication, even when administered by th nursing staff.[2]
- Eliminates the problem of missed, los or hidden doses. Prevents stockpiling.
- Assures regular medication intake.
- Lightens responsibilities of the hospita staff...simplifies patient management b obviating the need for multiple doses.
- Increases the likelihood of discharge In one study[3] of 24 long-term hospita patients treated with Prolixin Decanoat (Fluphenazine Decanoate Injec tion) every 7 days to 3 weeks:

DISCHARGED	CONSIDERED DISCHARGEABLE	NO IMPROVEMENT
13	4	7

Dischargeability "may also have been en hanced because the staff, the patien and the family were assured of an ac equate and regular medication intake."[3]

OD REASONS FOR CONTROLLED DRUG DELIVERY

leading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.

ntrolled drug delivery helps keep outpatient out

lelps assure continuity of medication makes prolonged remission more ely. With oral medication, on the er hand, "approximately 50% of all charged psychotic patients fail to take en the first dose of their outpatient dication."[2]

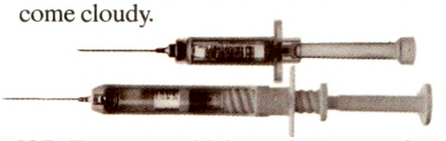
Enhances chances for rehabilitation... omotes acceptance socially, in the nily, and on the job because of sus- ined control of symptomatology.

Eases family adjustment by eliminating ncern about "taking his medicine."

Avoids the potential dangers of stock- ing, particularly for the suicidal.

Once administered, therapy cannot be ered by the patient, by his family, or anyone else.

The unique advantages of controlled ug delivery apply equally to the pa- nt who has never been hospitalized. They are advantages that can help make custodial care unnecessary as long as treatment continues.



Controlled drug delivery saves time, reduces cost in the hospital, clinic, office

Saves time in the hospital:

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Saves time in the clinic and in the office: Most patients report for their injections only once in every two-week period.

Prolixin Decanoate (Fluphenazine Decanoate Injection) also offers the convenience of easy-to-use Unimatic® Syringes: Unimatic single-dose preassembled syringes and Unimatic cartridge-needle units with a reusable plastic holder. Vials of 5 cc. Prolixin Decanoate are available for use with dry syringes and needles (at least 21 gauge). Use of a wet needle may cause the solution to become cloudy.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances, they are persistent—particularly in the case of tardive dyskinesia (see Adverse Reactions section of Brief Summary). Patients should be forewarned and reassured.

Controlled Drug Delivery *with* PROLIXIN® DECANOATE FLUPHENAZINE DECANOATE INJECTION)

For product Brief Summary, see following page.

SQUIBB HOSPITAL DIVISION

Controlled Drug Delivery
in schizophrenia with
PROLIXIN® DECANOATE
(FLUPHENAZINE DECANOATE INJECTION

BRIEF SUMMARY
Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy. Safety and efficacy in children have not been established because of inadequate experience in use in children.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 cc. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 cc. vials.

RECENT ADVANCES IN THE BIOLOGY OF SCHIZOPHRENIA *by* **Thomas A. Ban,** *McGill Univ., Montreal, Quebec, Canada.* New information on the biology of schizophrenia is presented here in a systematic and comprehensive manner. Neuroleptics have brought about fundamental changes in current concepts of schizophrenia that may lead to therapies which are based on theoretical principles. Students, practitioners and researchers in psychiatry will find the integration of these new informations in this monograph of great importance. *'73, 132pp., 6 il., 28 tables, $12.50*

BOOKS BOUND FOR YOUR SHELF

THE MALPRACTICE OF PSYCHIATRISTS: Malpractice in Psychoanalysis, Psychotherapy and Psychiatry *by* **Donald J. Dawidoff,** *New York City.* The author describes where possible areas of malpractice by psychiatrists and examines both the nature of and remedy for malpractice in the verbal therapies of psychoanalysis and psychotherapy. The specialized legal theories of breach of fiduciary duty, undue influence and words negligently spoken are applied to psychotherapy and psychoanalysis. *'73, 184 pp., $9.75*

CLINICAL USE OF PSYCHOTHERAPEUTIC DRUGS *by* **Leo E. Hollister,** *Stanford Univ. School of Medicine, Palo Alto, California.* Written for practicing physicians, psychiatrists and students who wish to learn how to better use drugs in the treatment of patients with emotional disorders. The book covers drug use in treating emotional disorders. Each class of drugs is considered in relation to the chemical and pharmacological differences among its members. *'73, 192 pp., 11 il., 13 tables, $6.95 cloth, $2.25 paper*

CRISIS INTERVENTION AND COUNSELING BY TELEPHONE *edited by* **David Lester,** *Stockton State College, Pomona, New Jersey, and* **Gene W. Brockopp,** *Suicide Prevention and Crisis Service, Buffalo, New York (23 Contributors)* Differentiation of telephone counseling, and its unique features, from other modes of counseling and proposed ways in which they can be handled are discussed. The selection and training of those who perform the counseling over the telephone, including the controversial development and increasing use of paraprofessionals is thoroughly analyzed. *'73, 336 pp., 6 il., 15 tables, $11.95*

SELF-DISCOVERY THROUGH SELF-EXPRESSION: Use of Art in Psychotherapy With Children and Adolescents *by* **Mala Betensky.** '73, 384 pp., 222 il. (32 in full color), $13.95

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe"
It need not be this way for the MBD child.
He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD —Minimal Brain Dysfunction—can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.

Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Ritalin®
(methylphenidate)
only when medication is indicated

CIBA

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized, and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

ntraindications: Known hypersensitivity; acute recovery phase following myocardial arction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe nvulsions, and deaths have occurred in patients receiving tricyclic antidepressant and AOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, minimum of 14 days should be allowed to elapse after the latter is discontinued. Protyline HCl should then be initiated cautiously with gradual increase in dosage until timum response is achieved.

rnings: May block the antihypertensive effect of guanethidine or similarly acting compunds. May impair mental and/or physical abilities required for the performance of hazards tasks, such as operating machinery or driving a motor vehicle. Should be used with ution in patients with a history of seizures and, because of its autonomic activity, in tients with a tendency to urinary retention or increased intraocular tension.

chycardia and postural hypotension may occur more frequently than with other antipressant drugs. Should be used with caution in elderly patients and patients with cardioscular disorders; such patients should be observed closely because of the tendency of e drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conction time. Myocardial infarction and stroke have occurred with drugs of this class. n rare occasions, hyperthyroid patients or those receiving thyroid medication ay develop arrhythmias when this drug is given.

age in Children: Not recommended for use in children because safety and effectiveness the pediatric age group have not been established.

age in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, se in pregnant women, nursing mothers, or women who may become pregnant requires at possible benefits be weighed against possible hazards to mother and child.

ecautions: When protriptyline HCl is used to treat the depressive component of schizorenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, epressed patients may experience a shift toward the manic phase; paranoid delusions, th or without associated hostility, may be exaggerated. In any of these circumstances, it ay be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug oncurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive agitated patients.

hen given with anticholinergic agents or sympathomimetic drugs, including epinephrine ombined with local anesthetics, close supervision and careful adjustment of dosages are equired. May enhance response to alcohol and effects of barbiturates and other CNS epressants. Possibility of suicide in depressed patients remains during treatment and ntil significant remission occurs; this type of patient should not have easy access to arge quantities of the drug. Concurrent administration with electroshock therapy may ncrease hazards of therapy; such treatment should be limited to patients for whom it is ssential. Discontinue drug several days before elective surgery, if possible. Both elevation nd lowering of blood sugar levels have been reported.

dverse Reactions: *Note:* Included in this listing are a few adverse reactions which have ot been reported with this specific drug. However, the pharmacologic similarities among he tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation nd anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning in humans. Animal studies have shown that physostigmine also reverses certain toxic effects of protriptyline, but to a lesser extent.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information.
Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

addendum

MSD
MERCK SHARP & DOHME

MSD 26 5 mg (orange)

MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

The balanced approach in adjunctive drug therapy

Especially relevant in psychiatric practice

Relief of obstructive anxiety through adjunctive drug therapy is often the means by which psychotherapeutic progress may resume. It is generally agreed, however, that for optimal benefit such anxiety should not be succeeded by a state of oversedation, with resultant flattening of emotional response.

For this reason, the benzodiazepines are widely preferred for reduction of excessive anxiety in psychoneurotic patients. They are considered among the safer, better-tolerated, less sedative of the effective antianxiety agents. In most cases, Librium (chlordiazepoxide HCl)—the first clinically applied benzodiazepine—provides the well-balanced effect frequently needed in treatment of overanxious office patients.

Librium (chlordiazepoxide HCl) dosage meets patient needs

The dosage schedule should have as its goal the relief of inappropriate anxiety. When that

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.,* operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of

Antianxiety effect without loss of affect

has been accomplished, Librium (chlordiazepoxide HCl) therapy should be reduced, then discontinued. Experience has shown that, in proper dosage, Librium seldom impairs mental acuity, a particular advantage for ambulatory patients who must continue to perform daily activities. (See Warnings section below.) As with all CNS-acting agents, however, patients receiving Librium should be cautioned against activities requiring complete mental alertness.

In most instances, Librium (chlordiazepoxide HCl) promptly reduces inappropriate anxiety to levels necessary for normal performance. Thereby it helps expedite the psychotherapeutic process by freeing the patient to retrieve the repressed material which must be explored if he is to resolve his emotional conflicts.

In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated. (See summary of product information below.)

for control of inappropriate anxiety

Librium®
(chlordiazepoxide HCl)

10-mg, 25-mg capsules t.i.d./q.i.d.

ROCHE

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

MENTAL HEALTH ON THE CAMPUS

By Raymond M. Glasscote
Michael E. Fishman
Clifford B. Reifler
James Raybin
Floyd D. Turner
Bernard L. Bloom
Samuel Pearlman
E. Robert Sinnett

". . . A most significant, objective explication of campus mental health. I endorse it wholeheartedly."
—Dana Farnsworth

In the hope of stimulating interest in creating support services for students experiencing any form of emotional or behavioral crisis, the Joint Information Service undertook to survey the numerous helping resources being provided at a selected group of colleges of widely varying characteristics. To do so it enlisted the talents of several of the most distinguished and accomplished practitioners in university mental health services. After extensive investigation, six schools outstanding for their mental health networks, plus a unique facility that contracts psychiatric treatment and consultation to more than a score of schools, were chosen for intensive study. Each program was visited by the authors, who interviewed not only the staff of the formal mental health services but representatives of the administration, housing, religious and many other kinds of activities and programs, faculty members, student leaders, and students who had utilized the mental health services. Consistently the interviews revealed some startling changes in campus interests and values during the year or two preceding the visits. In response to student demands, most of the schools had added seminars and lectures on marriage preparation and sexuality, with the result, at one school, of an almost ninety percent reduction in unplanned pregnancies. There was various tentative evidence that on the one hand drug usage, overall, had passed its peak, but on the other that marijuana use had been considerably incorporated into the social fabric of most of the schools.

The volume describes many specific services which support and enhance the emotional well-being of students. There are also detailed descriptions of the formal mental health services, including various approaches to individual and group treatment, medication, and provisions for hospitalization.

These and many other aspects of the emotional life of the campus are discussed in this volume, both in an overview of the contemporary college scene in America, and in detailed individual descriptions of the schools with their impressive range of supporting services.

1974 APA Appointment Books Desk and Pocket-sized

The "week-at-a-glance" Desk Appointment Book and the Pocket-sized version, published by the American Psychiatric Association, provide a quick and organized reference to your weekly engagements. As an added feature, it contains a comprehensive list of organizations and agencies of interest to psychiatrists and mental health professionals—in most cases director's name, address, phone number and date of forthcoming annual meeting are included. Also, there's a section to keep important phone numbers.

The Pocket-sized Appointment Book is 4″ × 7 1/2″, which is small enough to tuck inside your jacket, purse, suitcase or briefcase.

Desk: $5.00 ea.
Pocket: $3.00 ea.
Both: $7.00

Order 10 or more books for your colleagues or as gifts for your friends and take advantage of the 10% discount. Desk: $4.50 ea., Pocket-size: $2.70 ea. (15% discount for 100 or more copies)

Please send me
_____copy(ies) **Desk Appointment Book,** @$5.00 ea. order #141.
_____copy(ies) **Pocket Appointment Book,** @$3.00 ea. order #141-1.
_____set(s) **Desk & Pocket Appointment Book,** @$7.00 a set, order #141-2.
(10% discount for 10-99 copies; 15% discount for 100 or more copies.)

PSYCHIATRISTS

Hutchings Psychiatric Center has position available for well-trained, energetic Psychiatrists with clinical teaching and research interests. We are developing a new facility as a major part of a balanced system of service for five counties in Central New York. Our team Psychiatrist leads a 50-man multi-disciplinary team with inpatient, day care, and outpatient facilities. Hutchings Psychiatric Center is adjacent to Upstate Medical Center, and Syracuse University. Affiliated residents in psychiatry and family practice, as well as students in social work, rehabilitation, hospital administration, and psychiatric nursing provide teaching opportunities. A 14-man research staff is available for support of research interests.

Qualifications: Immediate openings are available for board eligible and board certified Psychiatrists. Salary range — $26,485 - $36,445 depending upon qualifications and experience.

Benefits: Vacation, Sick leave, personal leave, health insurance, dental insurance, New York State Retirement System, and major affiliation with S.U.N.Y. College of Medicine at Syracuse.

An Equal Opportunity Employer

CHILD PSYCHIATRY FELLOWSHIPS

New, Board Approved, Child Psychiatry Fellowships offered in an innovative, established clinical program. Outpatient, Community Child Psychiatry and Residential Treatment offer opportunities for a variety of treatment techniques. Crisis intervention ("life-space" interviews); behavioral therapy, pharmacotherapy; individual, group and family treatment methods; dynamic, social and developmental psychiatry taught. Learning by independent study, seminars, supervised experiences. Administrative experiences and training may be arranged. Multi-disciplinary staff including; six child psychiatrists, pediatrician, pediatric neurologist, psychologist, social workers, special education teachers, speech therapist, occupational therapists, recreational therapists and other consultants.

Program affiliated with the University of Michigan and a variety of clinical settings including; community mental health centers, child guidance clinics, etc. Salaries negotiable. Contact: William E. Kirk, M.D., Director, York Woods Center, Box A2, Ypsilanti, Michigan 48197. Phone: (313) 434-3400.

AN EQUAL OPPORTUNITY EMPLOYER

Help improv your depr cse patients' ability to cope.

In Brief:
Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.
Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.
Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.
Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.
Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychosi schizophrenic patients. Close supervision careful adjustment of dosage are required w this drug is given along with anticholinergi sympathomimetic drugs. While taking this d response to alcoholic beverages may be exag ated. There is limited clinical experience in concurrent administration of ECT and ant pressant drugs; thus, one should consider possibility of increased risk relative to bene Discontinue as soon as possible prior to elec surgery because of possible cardiovasc effects. Hypertensive episodes have b observed during surgery in patients on desi mine hydrochloride. Leukocyte and differe counts should be performed in any patient develops fever and sore throat during ther the drug should be discontinued if there is tropenia.
Adverse Reactions: *Cardiovascular:* hypo sion, hypertension, tachycardia, palpitat arrhythmias, heart block, myocardial infarct stroke. *Psychiatric:* confusional states (espec

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

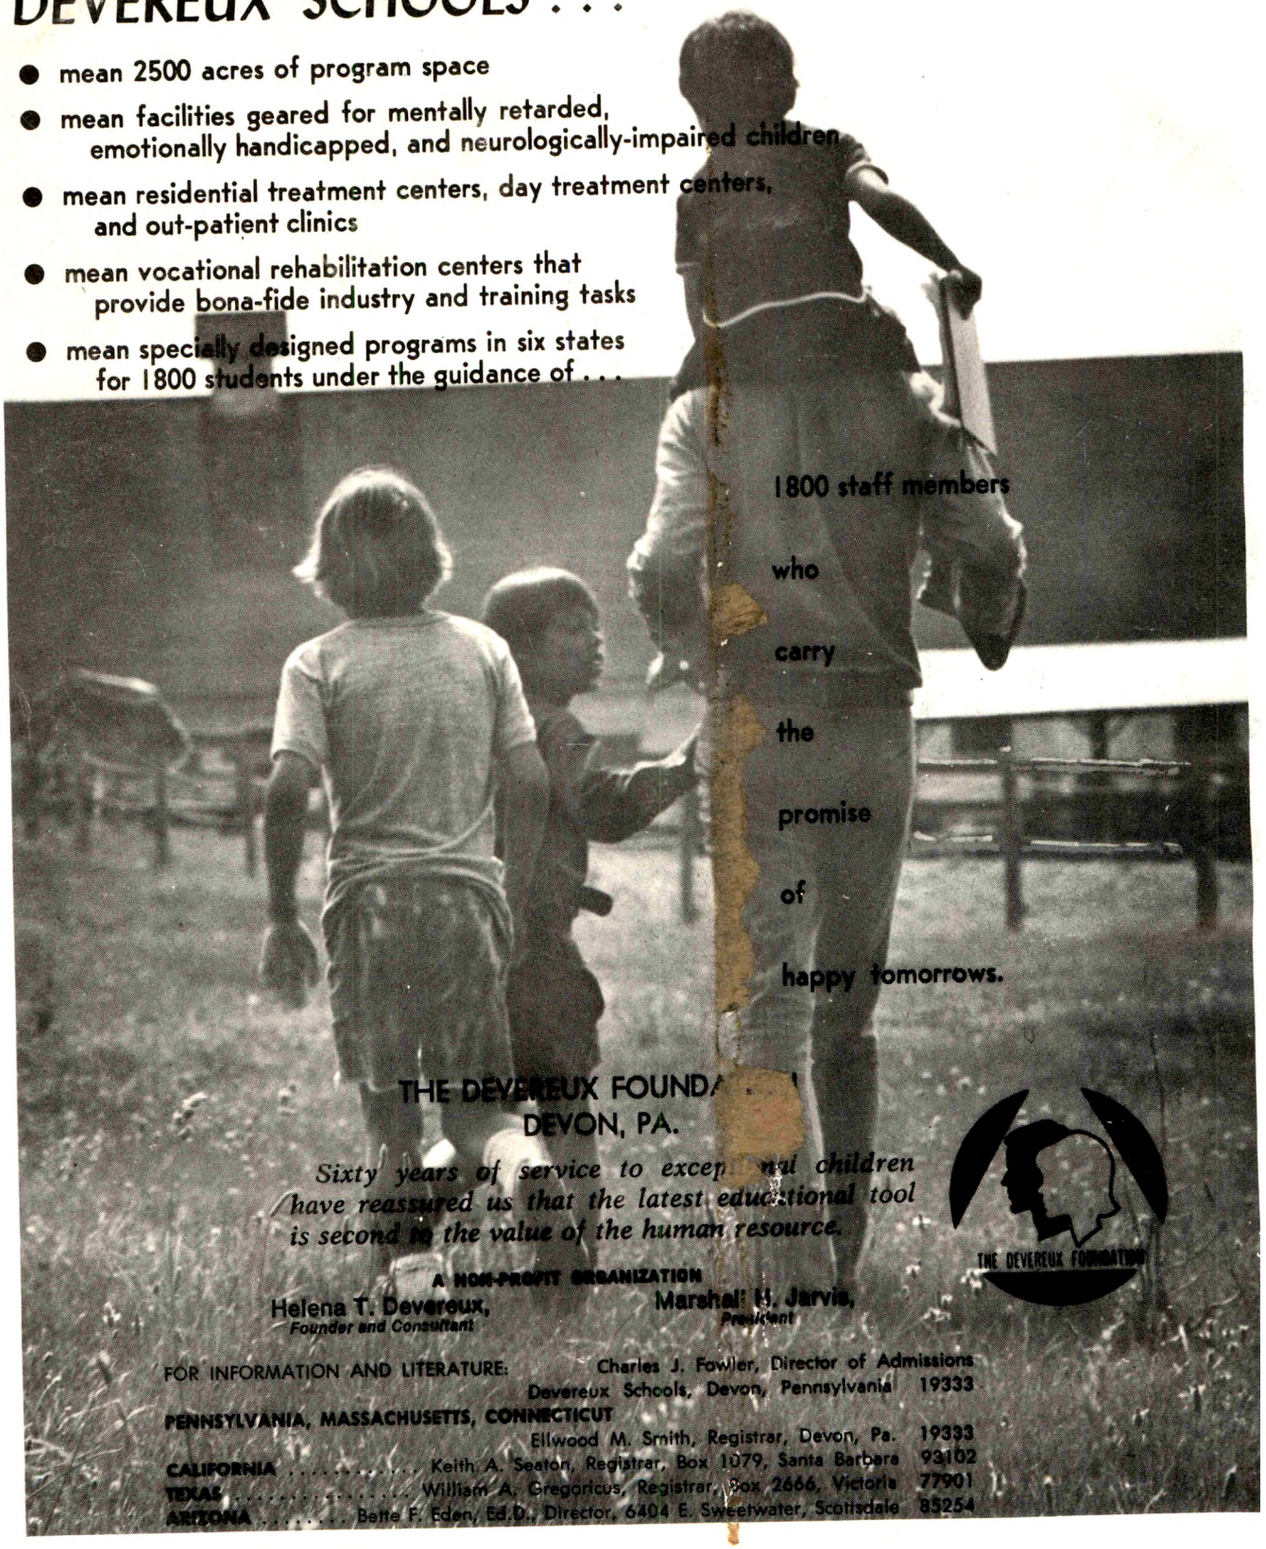
Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

n the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.



How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

The balanced approach in adjunctive drug therapy

Especially relevant in psychiatric practice

Relief of obstructive anxiety through adjunctive drug therapy is often the means by which psychotherapeutic progress may resume. It is generally agreed, however, that for optimal benefit such anxiety should not be succeeded by a state of oversedation, with resultant flattening of emotional response.

For this reason, the benzodiazepines are widely preferred for reduction of excessive anxiety in psychoneurotic patients. They are considered among the safer, better-tolerated, less sedative of the effective antianxiety agents. In most cases, Librium (chlordiazepoxide HCl)—the first clinically applied benzodiazepine—provides the well-balanced effect frequently needed in treatment of overanxious office patients.

Librium (chlordiazepoxide HCl) dosage meets patient needs

The dosage schedule should have as its goal the relief of inappropriate anxiety. When that

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of

Antianxiety effect without loss of affect

has been accomplished, Librium (chlordiazepoxide HCl) therapy should be reduced, then discontinued. Experience has shown that, in proper dosage, Librium seldom impairs mental acuity, a particular advantage for ambulatory patients who must continue to perform daily activities. (See Warnings section below.) As with all CNS-acting agents, however, patients receiving Librium should be cautioned against activities requiring complete mental alertness.

In most instances, Librium (chlordiazepoxide HCl) promptly reduces inappropriate anxiety to levels necessary for normal performance. Thereby it helps expedite the psychotherapeutic process by freeing the patient to retrieve the repressed material which must be explored if he is to resolve his emotional conflicts.

In general use, the most common side effects reported have been drowsiness, ataxia and confusion, particularly in the elderly and debilitated. (See summary of product information below.)

for control of inappropriate anxiety

Librium®
(chlordiazepoxide HCl)

10-mg, 25-mg capsules t.i.d./q.i.d.

ROCHE

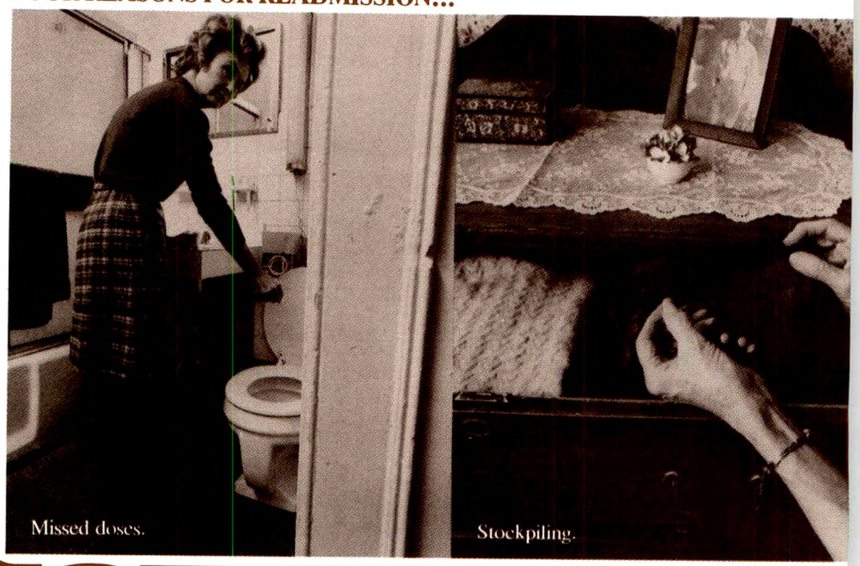
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

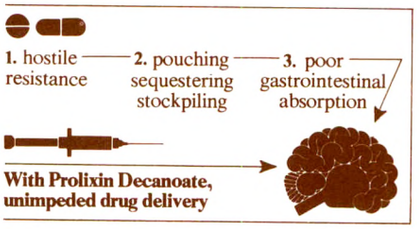
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

For schizophrenic patients...



A way out



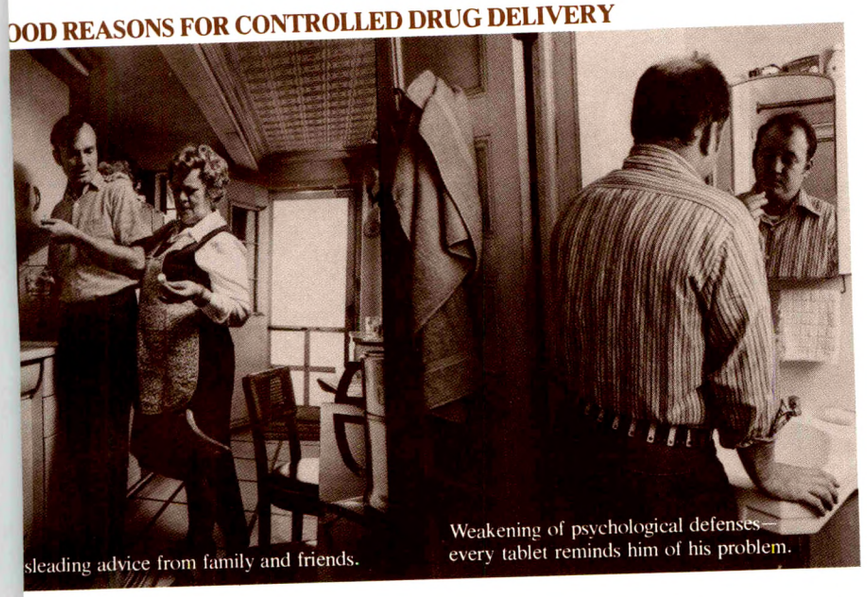
that helps them stay out

Controlled Drug Delivery with
PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)
Puts control of the schizophrenic in your hands with injections 1 to 3 weeks apart or longer, with an average duration of effect of about 2 weeks

Controlled drug delivery helps prevent disruption of therapy—one of the commonest causes of psychotic relapse. For the inpatient it means unimpeded drug delivery with improved chances of discharge.

FOUR REASONS FOR READMISSION...

For the outpatient it means improve chances for prolonged remission: "...th duration of remission and the incidenc of relapse are directly related to keepin the patient medicated after his return t the community."[1]



Controlled drug delivery helps the inpatient out

- Keeps the patient medicated...help make him more manageable, more cor fortable, and more amenable to tota treatment. With oral medication, on th other hand, approximately one out c every five patients does not take his me ication, even when administered by th nursing staff.[2]
- Eliminates the problem of missed, los or hidden doses. Prevents stockpiling.
- Assures regular medication intake.
- Lightens responsibilities of the hospita staff...simplifies patient management b obviating the need for multiple doses.
- Increases the likelihood of discharge In one study[3] of 24 long-term hospita patients treated with Prolixin Decanoat (Fluphenazine Decanoate Injec tion) every 7 days to 3 weeks:

DISCHARGED	CONSIDERED DISCHARGEABLE	NO IMPROVEMENT
13	4	7

Dischargeability "may also have been en hanced because the staff, the patien and the family were assured of an ac equate and regular medication intake."[3]

OOD REASONS FOR CONTROLLED DRUG DELIVERY

sleading advice from family and friends.

Weakening of psychological defenses—every tablet reminds him of his problem.

ontrolled drug delivery helps keep e outpatient out

Helps assure continuity of medication .makes prolonged remission more kely. With oral medication, on the her hand, "approximately 50% of all scharged psychotic patients fail to take ven the first dose of their outpatient edication."[2]

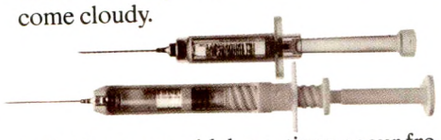
Enhances chances for rehabilitation... romotes acceptance socially, in the mily, and on the job because of sus- ained control of symptomatology.

Eases family adjustment by eliminating oncern about "taking his medicine."

Avoids the potential dangers of stock- iling, particularly for the suicidal.

Once administered, therapy cannot be ltered by the patient, by his family, or y anyone else.

The unique advantages of controlled rug delivery apply equally to the pa- ent who has never been hospitalized. They are advantages that can help make custodial care unnecessary as long as treatment continues.



Controlled drug delivery saves time, reduces cost in the hospital, clinic, office

Saves time in the hospital:

18 PATIENTS	18 PATIENTS
	
8 a.m. ¾ hr. 2 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 14 days for most patients
=2¼ hrs. nursing time	4 minutes required for each injection (approx.)
2¼ hrs. × 14 days **=31½ hrs. of nursing time every 14 days**	**=1 hr. 10 minutes nursing time in 14 days**
NURSING TIME SAVED IN 14 DAYS: 30 hours, 20 minutes[4]	

Saves time in the clinic and in the office: Most patients report for their injections only once in every two-week period.

Prolixin Decanoate (Fluphenazine Decanoate Injection) also offers the convenience of easy-to-use Unimatic® Syringes: Unimatic single-dose preassembled syringes and Unimatic cartridge-needle units with a reusable plastic holder. Vials of 5 cc. Prolixin Decanoate are available for use with dry syringes and needles (at least 21 gauge). Use of a wet needle may cause the solution to become cloudy.

N.B. Extrapyramidal reactions occur frequently. Most often they are reversible and can usually be controlled by administration of antiparkinsonian drugs. However, in some instances, they are persistent—particularly in the case of tardive dyskinesia (see Adverse Reactions section of Brief Summary). Patients should be forewarned and reassured.

Controlled Drug Delivery *with* PROLIXIN® DECANOATE (FLUPHENAZINE DECANOATE INJECTION)

For product Brief Summary, see following page.

SQUIBB HOSPITAL DIVISION

Controlled Drug Delivery

in schizophrenia with

PROLIXIN® DECANOATE

(FLUPHENAZINE DECANOATE INJECTION

BRIEF SUMMARY
Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per cc. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administered during pregnancy. Safety and efficacy in children have not been established because of inadequate experience in use in children.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with ulcer disease history since aggravation of peptic ulcer has occurred; in patients with history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams and reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight chang peripheral edema, abnormal lactation, gynec mastia, menstrual irregularities, false resul on pregnancy tests, impotency in men an increased libido in women have occurre in some patients on phenothiazine therap

Allergic Reactions—Itching, erythema, ur caria, seborrhea, photosensitivity, eczem and exfoliative dermatitis have been reporte with phenothiazines. The possibility of an phylactoid reactions should be borne in min

Hematologic—Blood dyscrasias includin leukopenia, agranulocytosis, thrombocyt penic or nonthrombocytopenic purpur eosinophilia, and pancytopenia have bee observed with phenothiazines. If soreness o the mouth, gums or throat or any symptom of upper respiratory infection occur and co firmatory leukocyte count indicates cellula depression, therapy should be discontinue and other appropriate measures institute immediately.

Hepatic—Liver damage manifested by ch lestatic jaundice, particularly during the firs months of therapy, may occur; treatmen should be discontinued. A cephalin floccul tion increase, sometimes accompanied by alterations in other liver function tests, ha been reported in patients who have had n clinical evidence of liver damage.

Others—Sudden deaths have been reporte in hospitalized patients on phenothiazine Previous brain damage or seizures may b predisposing factors. High doses should b avoided in known seizure patients. Shortly before death, several patients showed flar ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulm nating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial l sions. Although not a general feature of flu phenazine, potentiation of central nervous system depressants such as opiates, analg sics, antihistamines, barbiturates, and alco hol may occur.

Systemic lupus erythematosus-like syn drome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardio graphic and electroencephalographic tracings altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angio neurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 cc. Unimatic® single dose preassembled syringes and cartridge needle units, and 5 cc. vials.

SQUIBB HOSPITAL DIVISION

© 1973 E. R. Squibb & Sons, Inc. H423-023
Princeton, N. J. 08540

mirror, mirror on the wall, can this hospitalized schizophrenic relate to herself at all?

If the answer is "yes,"

then she can be helped to relate to others with the adjunctive use of

Trilafon®

brand of
perphenazine, NF

TRILAFON®
brand of perphenazine, NF
Tablets
REPETABS® Tablets
Syrup Concentrate Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON Injection should not be given to patients in coma or severely depressed states.

WARNINGS Usage in pregnancy: Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or oper machinery.

PRECAUTIONS As with any potent medication, patients receiving perphen should be under medical supervision, particularly if they are receiving doses. Patients who have had any severe reaction to phenothiazines or to pramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in pat treated with perphenazine, the possibility that they might occur with TRIL should be considered; blood dyscrasias (pancytopenia, thrombocytopenic pur leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the v fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyph photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, bu epinephrine, because epinephrine's action is blocked and partly reversed by phenazine. Severe, acute hypotension has occurred with the use of phen zines and is of particular concern in patients with mitral insufficienc pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic rea to perphenazine; treatment with perphenazine should be stopped if this oc

The antiemetic effect of perphenazine can obscure signs of toxicity du overdosage of other drugs, or mask the symptoms of disease (eg, brain tum intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; there contact of hands or clothing by those handling perphenazine solutions sl be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-sys depressant actions of opiates, antihistamines, barbiturates, and alcohol,

Schering

Tablets 2,4,8,16 mg. REPETABS® 8 mg.	for maintenance therapy with cooperative patients
Concentrate 16 mg./5 cc. 4 oz. bottle with calibrated dropper	for "cheeking," geriatric, confused or otherwise untrustworthy psychotic patients
Injection 5 mg./cc., 10 cc. multiple-dose vial, 1 cc. ampule	for emergency or initial treatment of agitated psychotics

A potent phenothiazine to help:

- maintain alertness level
- stabilize behavioral patterns
- relieve anxiety/agitation
- increase patient response to psychotherapy

Trilafon®

brand of

perphenazine, NF

a major tranquilizer for in-hospital control and take-home therapy

---

the usual dosage of these agents is required when they are administered imitantly with TRILAFON. Patients should be cautioned that their response cohol may be increased while they are being treated with TRILAFON.
enothiazines also potentiate the effects of atropine, heat, and phosphorus ticides, and should be used with caution in persons exposed to these agents.

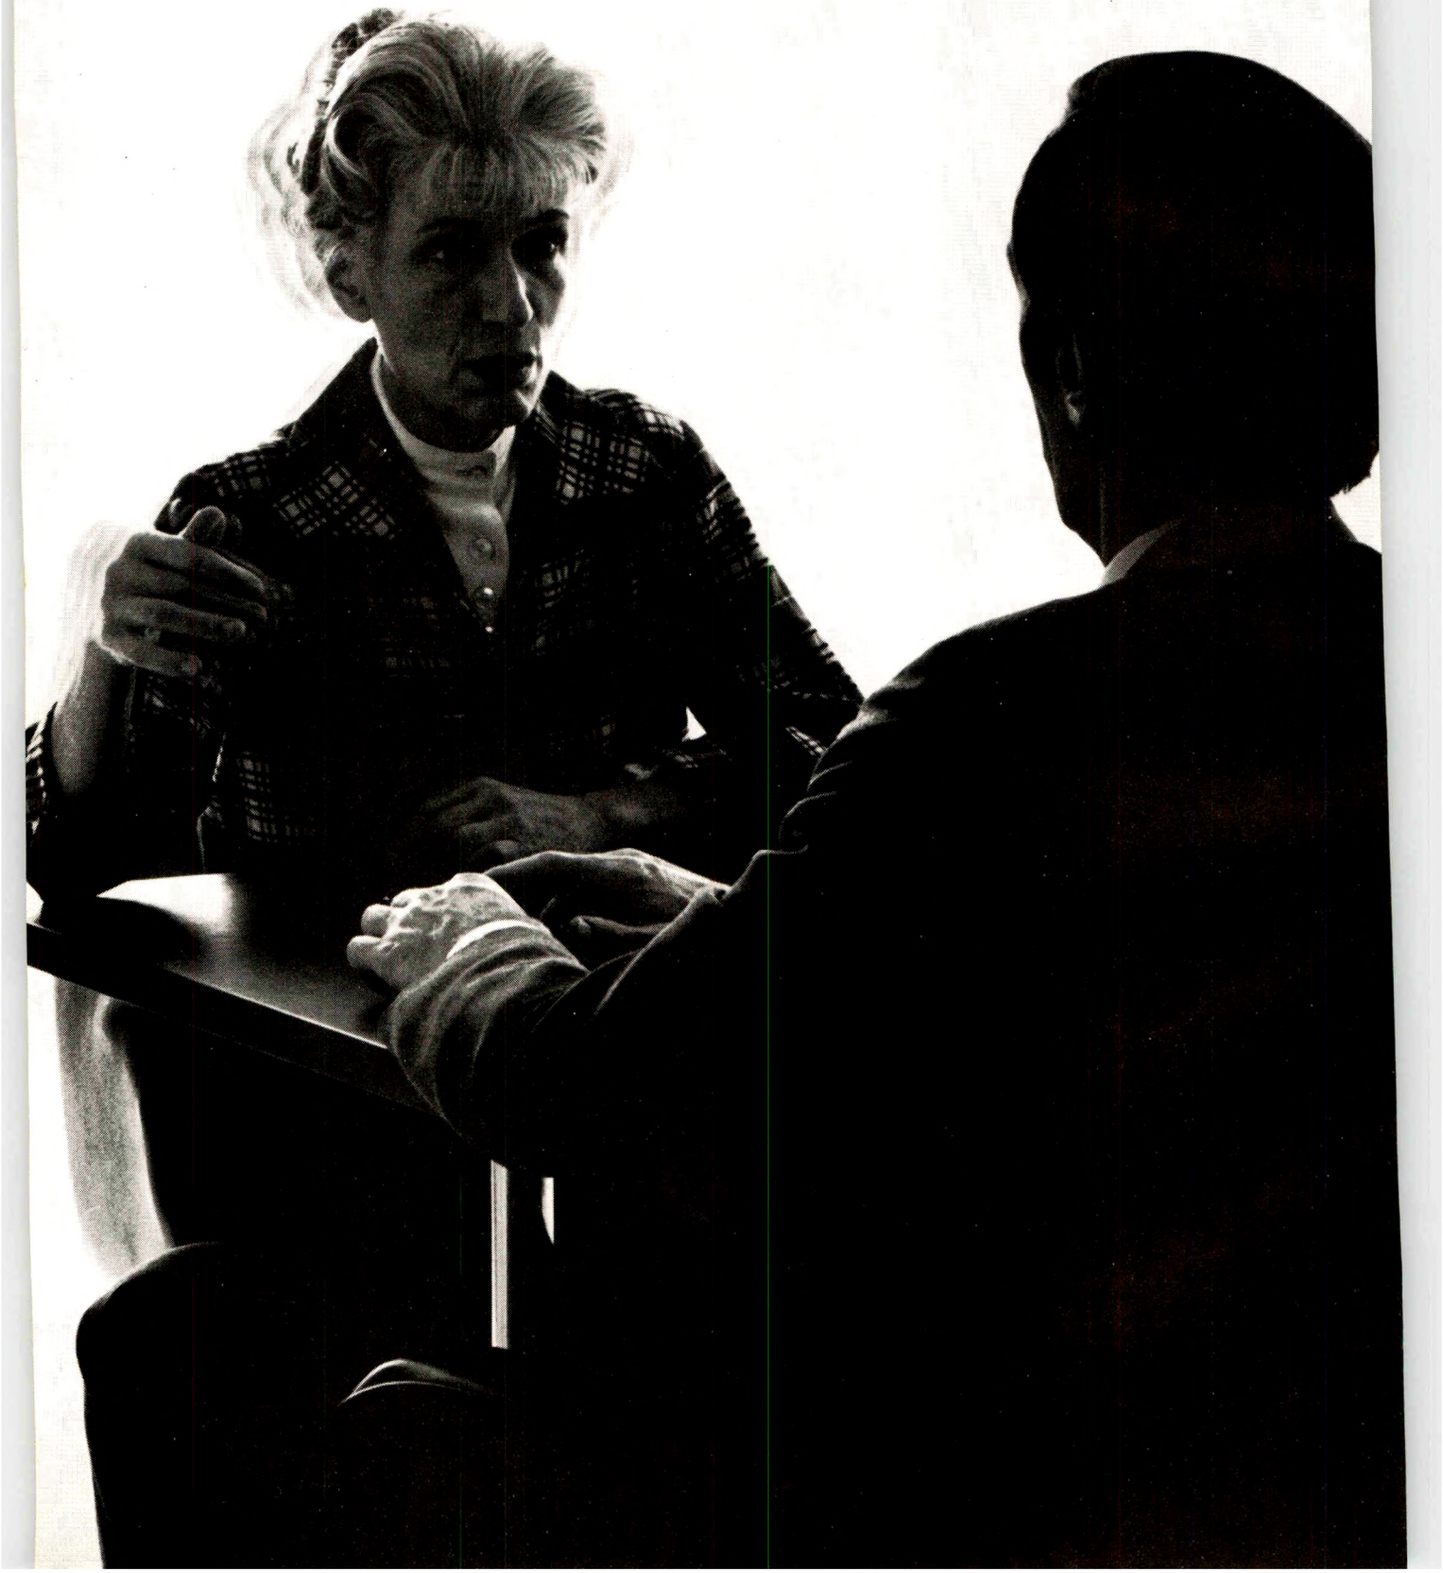
RSE REACTIONS *Extrapyramidal reactions:* dystonia including protru- discoloration, aching and rounding of the tongue; tonic spasm of the mas- ory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric , trismus, torticollis, retrocollis, muscle weakness, and aching and numb- of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; reflexia; and ataxia. The incidence and severity of these reactions usually ase with increased dosage, but have occurred in some patients receiving losage. Reduction in dosage or treatment with an antispasmodic agent will ly control extrapyramidal reactions. In some instances, however, these ions may persist after discontinuation of treatment with perphenazine.
rsistent tardive dyskinesia: As with all antipsychotic agents, tardive dys- ia may appear in some patients on long-term therapy or may appear after therapy has been discontinued. The risk appears to be greater in elderly nts on high-dose therapy, especially females. The symptoms are persistent n some patients appear to be irreversible. The syndrome is characterized by mical involuntary movements of the tongue, face, mouth or jaw (eg, pro- on of tongue, puffing of cheeks, puckering of mouth, chewing movements). etimes these may be accompanied by involuntary movements of extremities. e is no known effective treatment for tardive dyskinesia; antiparkinsonism ts usually do not alleviate the symptoms of this syndrome. It is suggested all antipsychotic agents be discontinued if these symptoms appear. Should necessary to reinstitute treatment, or increase the dosage of the agent, or h to a different antipsychotic agent, the syndrome may be masked. It has reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON Injection have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON Injection is a rare occurrence.



NOVEMBER 1972

Schering

Schering Corporation, Bloomfield, N.J. 07003

SWW-270

patients most in need of phenothiazines are often least able to cope with their side effects

TABLETS: 0.5 mg, 1 mg, and 2 mg
INJECTION: 1.0 mg/ml

COGENTIN®
(Benztropine Mesylate | MSD)

added to the regimen helps alleviate phenothiazine-induced extrapyramidal symptoms

In a recent study of 71 patients treated with antipsychotics, COGENTIN, administered in a double-blind manner in various dosage schedules, was found to be highly successful in relieving phenothiazine-induced extrapyramidal symptoms.[1] Patients experienced relief of such symptoms as facial and hand tremors, muscle weakness, sensations of psychic and motor excitation, and akathisia.

1. Neu C, Dimascio A, Demirgian E: Antiparkinson medication in the treatment of extrapyramidal side effects: single or multiple daily doses? Curr Ther Res *14*:246, May 1972.

Contraindications: Children under three years of age; use cautiously in older children.

Warnings: Safe use in pregnancy not established. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle.

Precautions: Because of cumulative action, continued supervision is advisable. Closely observe patients with tendencies to tachycardia or hypotension and those with prostatic hypertrophy. Dysuria may occur, but rarely becomes a problem. Large doses may cause complaints of weakness and inability to move particular muscle groups, requiring dosage adjustment.

Mental confusion and excitement may occur with large doses, or in susceptible patients; visual hallucinations reported occasionally. May intensify mental symptoms when used to treat extrapyramidal disorders due to CNS drugs, such as reserpine and phenothiazines, in patients with mental disorders; in such patients, increased doses of antiparkinsonian drugs can precipitate toxic psychosis; observe patients carefully, especially at the beginning of treatment or if dosage is increased. Masking action on possible development of permanent extrapyramidal symptoms with prolonged phenothiazine therapy has not been investigated. Patients with a poor mental outlook are usually poor candidates for therapy.

May produce anhidrosis; give with caution during hot weather, especially to the old, the chronically ill, the alcoholic, those who have central nervous system disease, those who do manual labor in a hot environment, and those with disturbances in sweating. If anhidrosis appears, reduce dosage so that ability to maintain body heat equilibrium is not impaired. Occurrence of glaucoma is a possibility; probably should not be used in angle-closure glaucoma.

Large doses generally cannot be tolerated by older patients, thin patients, or patients with arteriosclerotic parkinsonism. Do not terminate other antiparkinsonism agents abruptly; reduce gradually. In drug-induced parkinsonism, closely observe patients for severe reactions, and temporarily discontinue COGENTIN (Benztropine Mesylate, MSD) if they appear; do not extend therapy longer than necessary to counteract the extrapyramidal disorders; although the psychotropic drug frequently can be continued without change of dosage, a decrease might be indicated.

Adverse Reactions: Adverse reactions may be anticholinergic and/or antihistaminic. Dry mouth, blurred vision, nausea, nervousness may develop. If dry mouth causes difficulty in swallowing or speaking, or loss of appetite and weight, reduce dosage, or discontinue drug temporarily. Vomiting occurs infrequently and may be controlled by temporary discontinuation, followed by resumption at a lower dosage. Constipation, numbness of the fingers, listlessness, and depression may develop. Occasionally, an allergic reaction, e.g., skin rash, develops; sometimes this can be controlled by reducing dosage, but occasionally requires discontinuation.

Supplied: Tablets in three strengths: 0.5 mg and 1 mg benztropine mesylate, in bottles of 100, and 2 mg benztropine mesylate, in bottles of 100 and 1000. Injection, containing 1.0 mg benztropine mesylate and 9.0 mg sodium chloride per ml, in 2-ml ampuls.

For more detailed information, consult your MSD representative or see full prescribing information. Merck Sharp & Dohme, Division of Merck & Co., INC., West Point, Pa. 19486

MSD
MERCK SHARP & DOHME

addendum

Facts about dosage schedules of COGENTIN (Benztropine Mesylate | MSD) in treating drug-induced extrapyramidal symptoms

In treating extrapyramidal symptoms due to central nervous system drugs, such as reserpine and phenothiazines, the recommended dosage of COGENTIN is 1 to 4 mg once or twice a day orally or parenterally. The tablet form should be used when patients are able to take oral medication.

When extrapyramidal symptoms develop soon after initiation of phenothiazine treatment, they are likely to be transient. One to 2 mg COGENTIN orally two or three times a day usually provides relief within one or two days. After one or two weeks, COGENTIN should be withdrawn to determine the continued need for it. If symptoms recur, COGENTIN can be reinstituted.

Extrapyramidal symptoms that develop slowly usually are less responsive. They may require more prolonged treatment with 2 to 6 mg a day.

For more detailed information, see full prescribing information.

Director

Out-Patient Service: $28,000 - $32,100

Thistletown Regional Centre for Children and Adolescents, MINISTRY OF HEALTH, located in northwestern Metro Toronto, requires a Senior Child Psychiatrist to assume leadership of the Out-Patient and Community Services.

The Centre provides in-patient, out-patient and day treatment services to emotionally disturbed children and adolescents and is affiliated with the Department of Psychiatry, University of Toronto, as a training centre in child psychiatry. The Out-Patient Department has been enlarged with a new wing with modern teaching facilities.

Alternative professional contract engagement also available at $27,000-$34,000 per annum.

Qualifications: Licensed to practice in Ontario or eligible for such license; certification by the Royal College of Physicians and Surgeons in Psychiatry or eligible for such certification; considerable child psychiatric clinical experience.

Please write to: **Clinical Director, Thistletown Regional Centre for Children and Adolescents, 11 Farr Avenue, Rexdale, Ontario, Canada. M9V 2A5**

Judd Marmor on

The Future of

Psychoanalytic Therapy

Agitated and hyperactive?...Or cooperative?

While psychotic symptoms remain acute, the barrier between you and the agitated, hyperactive patient may be insurmountable. Prompt intervention with HALDOL (haloperidol) often makes it possible for you to reach... relate...rehabilitate.

And rapport with such patients is further enhanced because HALDOL usually leaves patients alert and relatively non-sedated.

cooperation often begins with

HALDOL® (haloperidol)

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

© MCNEIL LABORATORIES, INC., 1973

Haldol®
(HALOPERIDOL)
a first choice for prompt rapport

A Dosage Form for Every Need:

4 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg. and 5 mg.

An undetectable, tasteless Liquid Concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting Injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Summary of Directions for Use

Indications: HALDOL (haloperidol) is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's Syndrome.

Contraindications: HALDOL (haloperidol) is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL (haloperidol) in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of HALDOL orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL (haloperidol), decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL (haloperidol) should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, *epinephrine should not be used* since HALDOL may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant anti-Parkinson medication is required, it may have to be continued after haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including anti-Parkinson agents, are administered concomitantly with HALDOL. When HALDOL is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of anti-Parkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL (haloperidol) is administered or prescribed. 6/73

an inexpensive way to "write"
chlorpromazine

CHLOR-PZ™

BRAND OF

CHLORPROMAZINE HCl

The cost of chlorpromazine has been reduced. Introducing CHLOR-PZ, a quality chlorpromazine at a lower price. You can prescribe CHLOR-PZ in a wide variety of strengths for your patients. And who knows... maybe they'll be just a little less disturbed knowing their prescription costs less.

CHLOR-PZ.
It lowers the price of long-term therapy.

USV Pharmaceutical Corp.
Tuckahoe, N.Y. 10707

Indications: Certain manifestations of psychotic disorders; nausea and vomiting; restlessness and apprehension prior to surgery; acute intermittent porphyria; as adjunct in tetanus treatment.
Contraindications: Comatose states, presence of large amounts of CNS depressants, bone marrow depression, or hypersensitivity to phenothiazines.
Warnings: Caution patients about performing hazardous tasks (e.g., operating vehicles or machinery). Avoid concomitant use with alcohol or other CNS depressants. May counteract antihypertensive effect of guanethidine and related compounds. Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. In rodents, embryotoxicity, increased neonatal mortality, and nursing transfer of the drug have been observed, with the possibility of permanent neurological damage. Use with extreme caution in presence of glaucoma or prostatic hypertrophy.
Precautions: Use cautiously in persons with cardiovascular, liver, acute or chronic respiratory disease (particularly children), or with a history of epilepsy. Due to cough reflex suppression, aspiration of vomitus and mucus is possible. May prolong or intensify the action of CNS depressants (reduce dosage of concomitant CNS depressants), organophosphate insecticides, heat, atropine and related drugs. Anticonvulsant action of barbiturates is not intensified. May block or reverse epinephrine action. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.
Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, faintness, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes including blunting of T waves and prolonged Q-T interval; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent dyskinesia, tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states; cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions, photosensitivity, exfoliative dermatitis, contact dermatitis; asthma, laryngeal edema, angioedema, anaphylactoid reactions; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, infertility; gynecomastia, changes in libido in males; hypercholesterolemia; dry mouth, nasal congestion, constipation, adynamic ileus, miosis, mydriasis; hyperpyrexia; increased appetite and weight; urinary retention, peripheral edema; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment.
Note: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.
How Supplied: CHLOR-PZ tablets—10, 25, 50, 100 and 200 mg., in bottles of 100 and 1000.

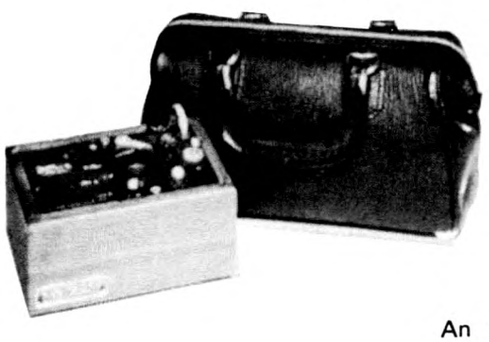
PHARMACEUTICALS

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

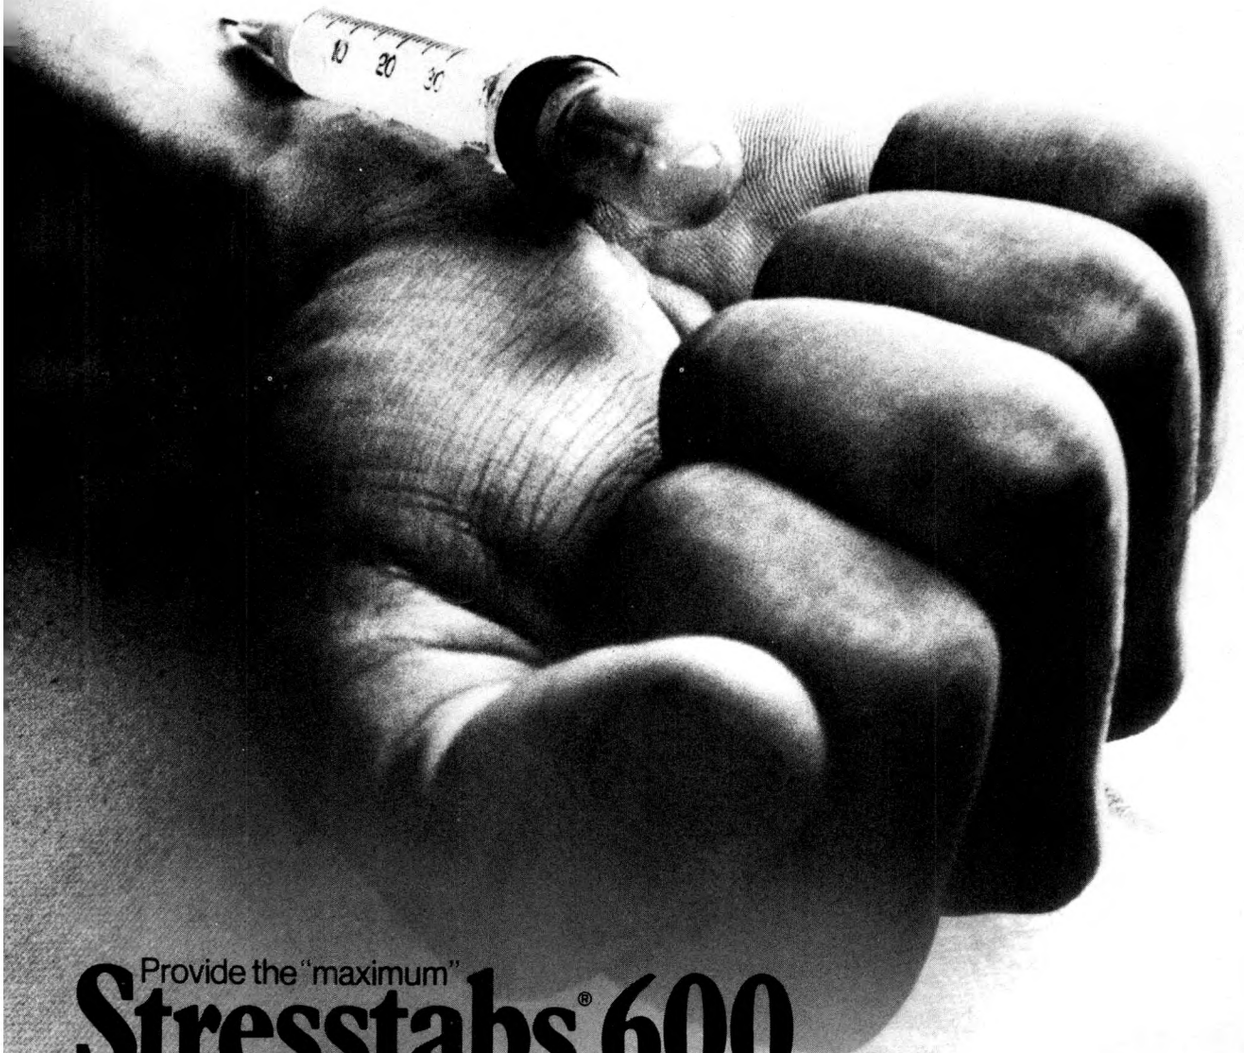
The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.



An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

A22

A HEAD START FOR THE CLINICALLY DEPRESSED PATIENT.

All tricyclic antidepressants take om one to four weeks before optimal ntidepressant effect is seen.

Sinequan (doxepin HCl)—the newest icyclic antidepressant—is no exception.

But, in that waiting period, Sinequan ffers the clinically depressed atient both:

prompt sedative activity to begin relieving the sleep disturbances often characteristic of depression, and

marked antianxiety activity to help relieve the apprehension, tension, worry and fear that usually accompany depression.

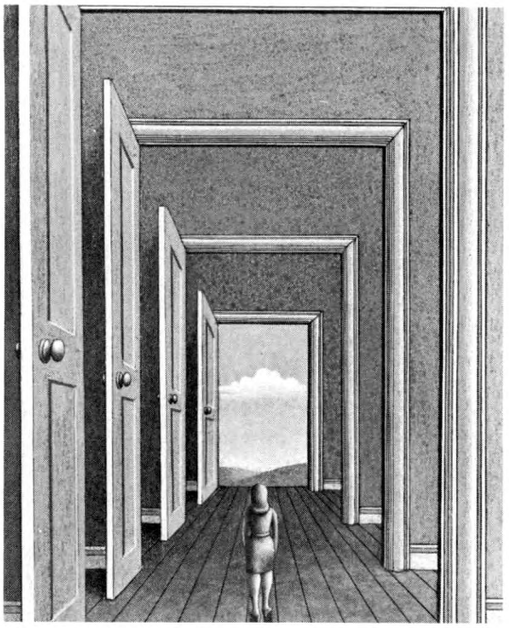
Further, the incidence of cardiovascular side effects with Sinequan is relatively low. Tachycardia and hypotension are infrequent. (Drowsiness is the most common side effect.) And Sinequan, unlike other tricyclic antidepressants, does not generally affect the activity of guanethidine and similarly acting compounds at usual clinical doses.

Prompt sedative activity. Marked antianxiety activity. Low incidence of cardiovascular side effects.

It's a head start for the clinically depressed patient.

HE NEWEST TRICYCLIC ANTIDEPRESSANT– VITH DIFFERENCES YOU CAN SEE.

Sinequan®
)OXEPIN HCl
5-mg. and 50-mg. capsules



Pfizer **LABORATORIES DIVISION**
PFIZER INC.

(See Brief Summary on following page for information on adverse reactions, contraindications, warnings and precautions.)

3, PFIZER INC.

Sinequan®
DOXEPIN HCl
25-mg. and 50-mg. capsules

THE NEWEST TRICYCLIC ANTIDEPRESSANT–WITH DIFFERENCES YOU CAN SEE.

BRIEF SUMMARY
Sinequan®(doxepin HCl) **Capsules**
Contraindications. Sinequan (doxepin HCl) is contraindicated in individuals who have shown hypersensitivity to the drug.

Sinequan (doxepin HCl) is contraindicated in patients with glaucoma or a tendency to urinary retention.

Warnings. *Usage in Pregnancy:* Sinequan (doxepin HCl) has not been studied in the pregnant patient. It should not be used in pregnant women unless, in the judgment of the physician, it is essential for the welfare of the patient, although animal reproductive studies have not resulted in any teratogenic effects.

Usage in Children: The use of Sinequan (doxepin HCl) in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with Sinequan (doxepin HCl). The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Although Sinequan (doxepin HCl) has significant tranquilizing activity, the possibility of activation of psychotic symptoms should be kept in mind.

Other structurally related psychotherapeutic agents (e.g., iminodibenzyls and dibenzocycloheptenes) are capable of blocking the effects of guanethidine and similarly acting compounds in both the animal and man. Sinequan (doxepin HCl), however, does not show this effect in animals. At the usual clinical dosage, 75 to 150 mg. per day, Sinequan (doxepin HCl) can be given concomitantly with guanethidine and related compounds without blocking the antihypertensive effect. At doses of 300 mg. per day or above, Sinequan (doxepin HCl) does exert a significant blocking effect. In addition, Sinequan (doxepin HCl) w similar to the other structurally related psychotherapeutic agents as regards i ability to potentiate norepinephrine response in the animal. However, in t human this effect was not seen. This is in agreement with the low incidence the side effect of tachycardia seen clinically.

Adverse Reactions. *Anticholinergic Effects:* Dry mouth, blurred vision, and co stipation have been reported. They are usually mild, and often subside wi continued therapy or reduction of dose.

Central Nervous System Effects: Drowsiness has been observed. This usual occurs early in the course of treatment, and tends to disappear as therapy continued.

Cardiovascular Effects: Tachycardia and hypotension have been reporte infrequently.

Other infrequently reported side effects include extrapyramidal symptoms, gas trointestinal reactions, secretory effects such as increased sweating, weakness dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus photophobia, decreased libido, rash, and pruritus.

Dosage. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increase or decreased at appropriate intervals and according to individual response. Th usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

Supply. Sinequan (doxepin HCl) is available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., and 50 mg. of doxepin in bottles of 100 and 1000.

More detailed professional information available on request.

OXFORD

Brain's Clinical Neurology

Fourth Edition

Revised by ROGER BANNISTER, St. Mary's Hospital, London. ☐ In this revision Dr. Bannister has paid particular attention to two areas: virus diseases of the nervous system and "geographical neurology." New material on genetic mechanisms, optic atrophy, physiology of the cerebral circulation and the histochemistry of muscle disease has been added. The text describes new isotope techniques for measuring cerebral blood flow, and myelographic techniques using air and the supine position.

1973 456 pp. 136 illus. cloth $18.50 paper $11.50

Society, Stress and Disease

Volume I: The Psychosocial Environment and Psychosomatic Diseases

Edited by LENNART LEVI, M.D., Karolinska Hospital, Stockholm ☐ "The book presents a multitude of problems in a comprehensive and stimulating fashion. . . . It should be worthwhile reading for any physician interested in the welfare of his patient and the factors that might influence his health. The book widens our horizons by bringing into focus problems that must be solved if we are to live in harmony with changing social forces." —William Ransohoff, M.D., *Annals of Internal Medicine*

1972 480 pp. 134 illus. $29.95

Early Human Development

Edited by S. J. HUTT and CORINNE HUTT, both of the University of Keele. ☐ These twenty-nine articles, with linking text, trace human development during the first four years of life, a time when biological factors are especially powerful, and during which the foundations of later intellect and personality are laid. Readings have been chosen not only from psychological, but also from biological, endocrinological, and physiological sources.

1973 372 pp. 55 illus. paper $9.50

An Introduction to Psychopathology

Third Edition

D. RUSSELL DAVIS, University of Bristol. ☐ For psychiatrists seeking explanations for their clinical problems and psychologists seeking practical applications for their research work, this text will bridge the gap between the psychiatric clinic and the psychological laboratory. The volume explains mental disorders in psychological terms and by reference to family processes and social experience.

1973 180 pp. paper $5.95

Interviewing and Patient Care

ALLEN J. ENELOW, M.D., Pacific Medical Center, University of the Pacific, and SCOTT N. SWISHER, M.D., Michigan State University, College of Human Medicine. ☐ "Very well organized text for first year medical students—especially helpful because of the material on the problem oriented record and on interviewing of children and families as well as usual adult patient interviewing."—Donald G. Langsley, M.D., University of California Davis School of Medicine

1972 240 pp. cloth $7.50 paper $3.95

Behavior Modification of the Mentally Retarded

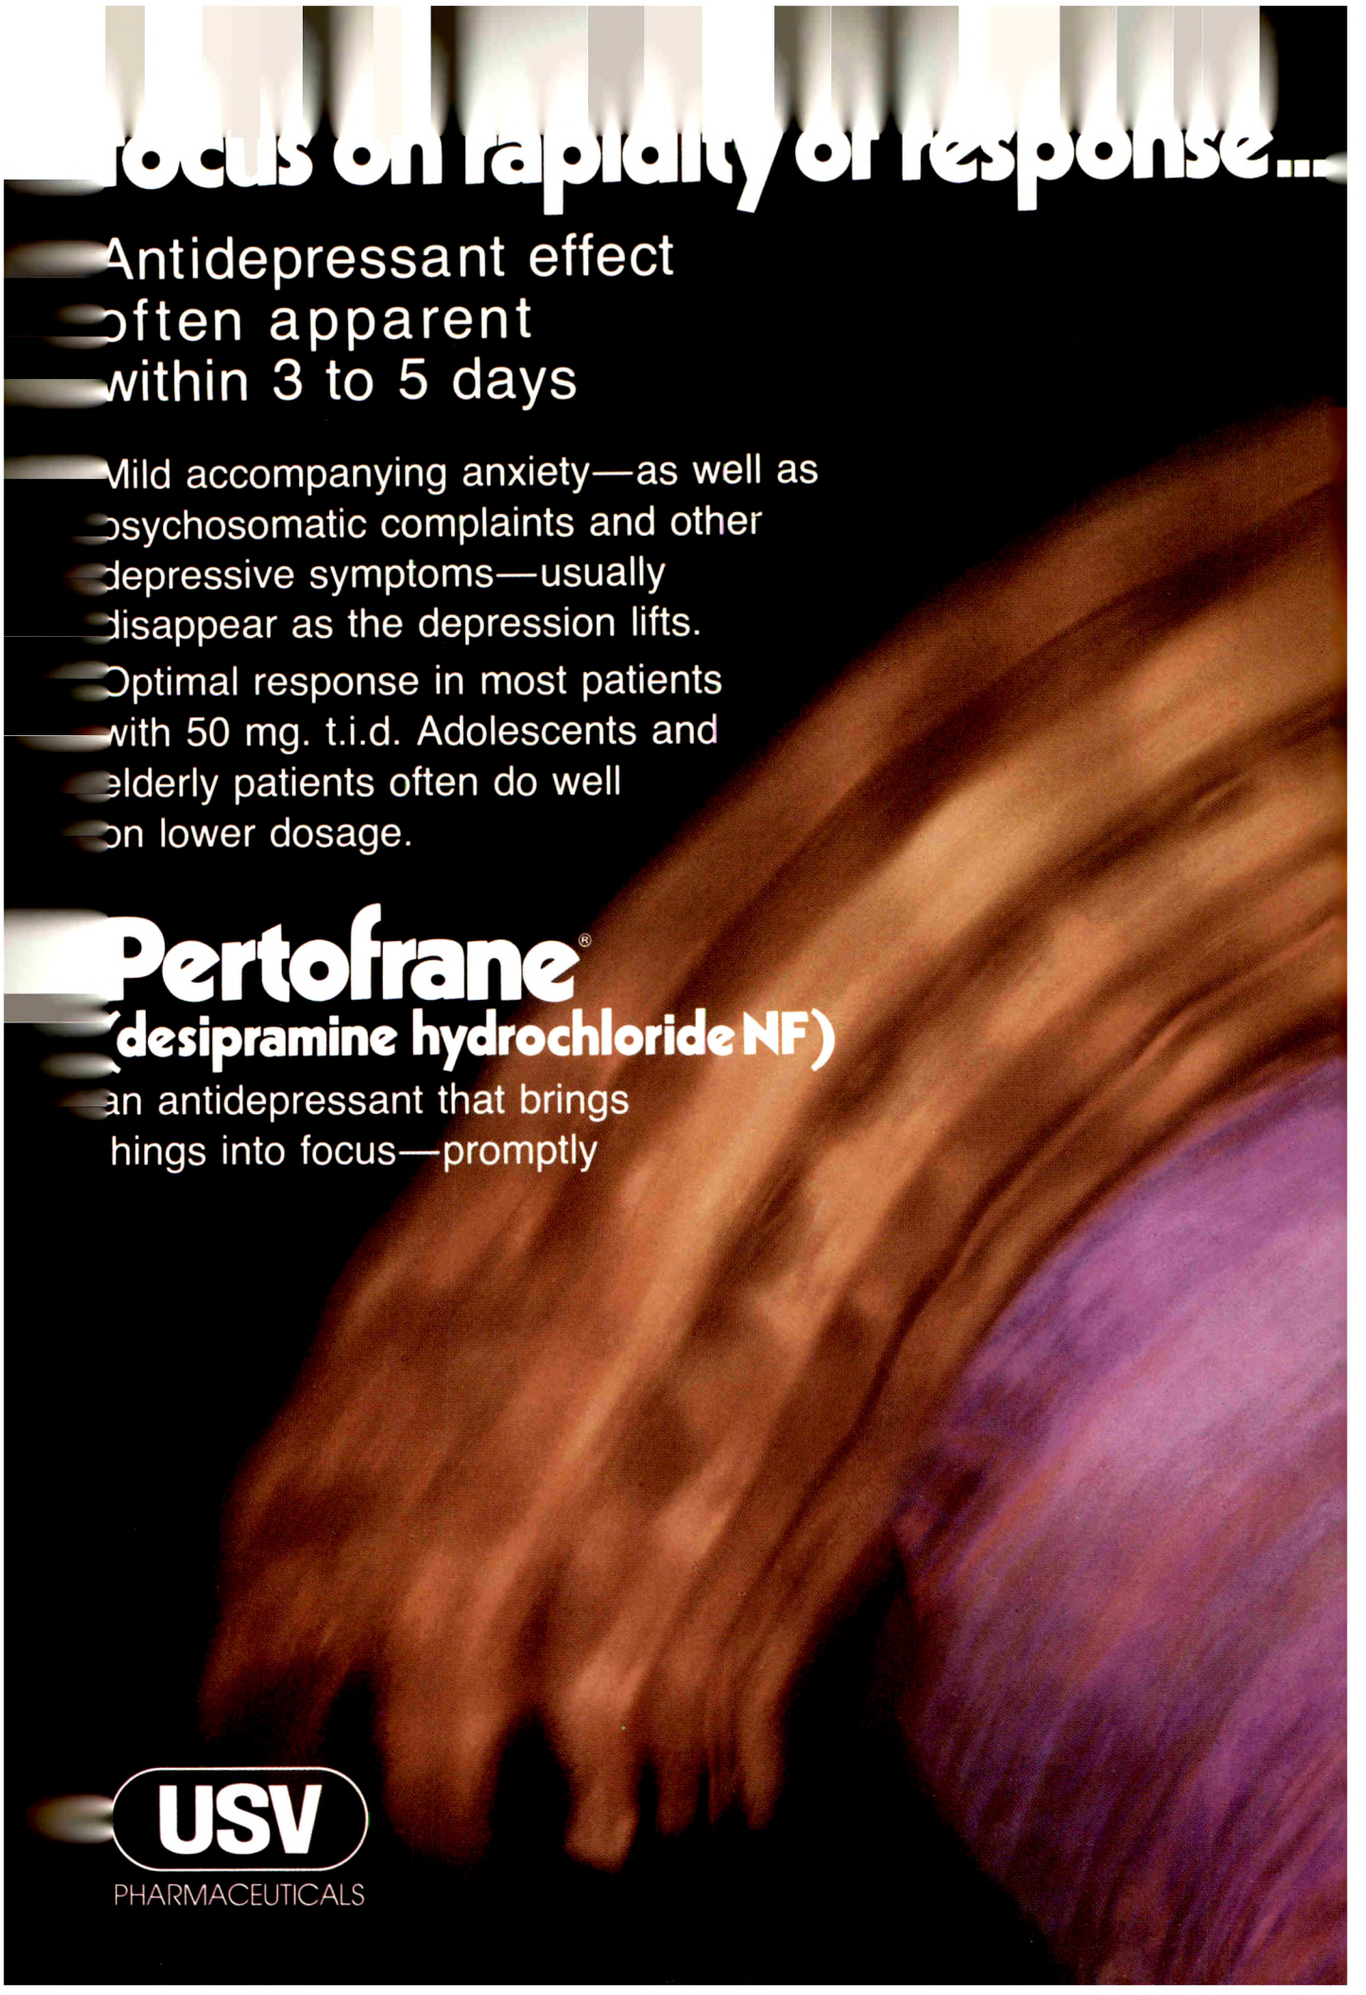
Edited by TRAVIS THOMPSON, University of Minnesota, and JOHN GRABOWSKI, University of Southern California. ☐ This is an excellent book which should be read by everyone who works with retarded people in residential or day care settings."—Robert C. Colligan, *Mayo Clinic Proceedings*. "This is an important book of great consequence to those working in the field of mental handicap."—B. H. Kirman, *British Journal of Psychiatry*

1972 320 pp. Cloth $7.50 paper $4.95

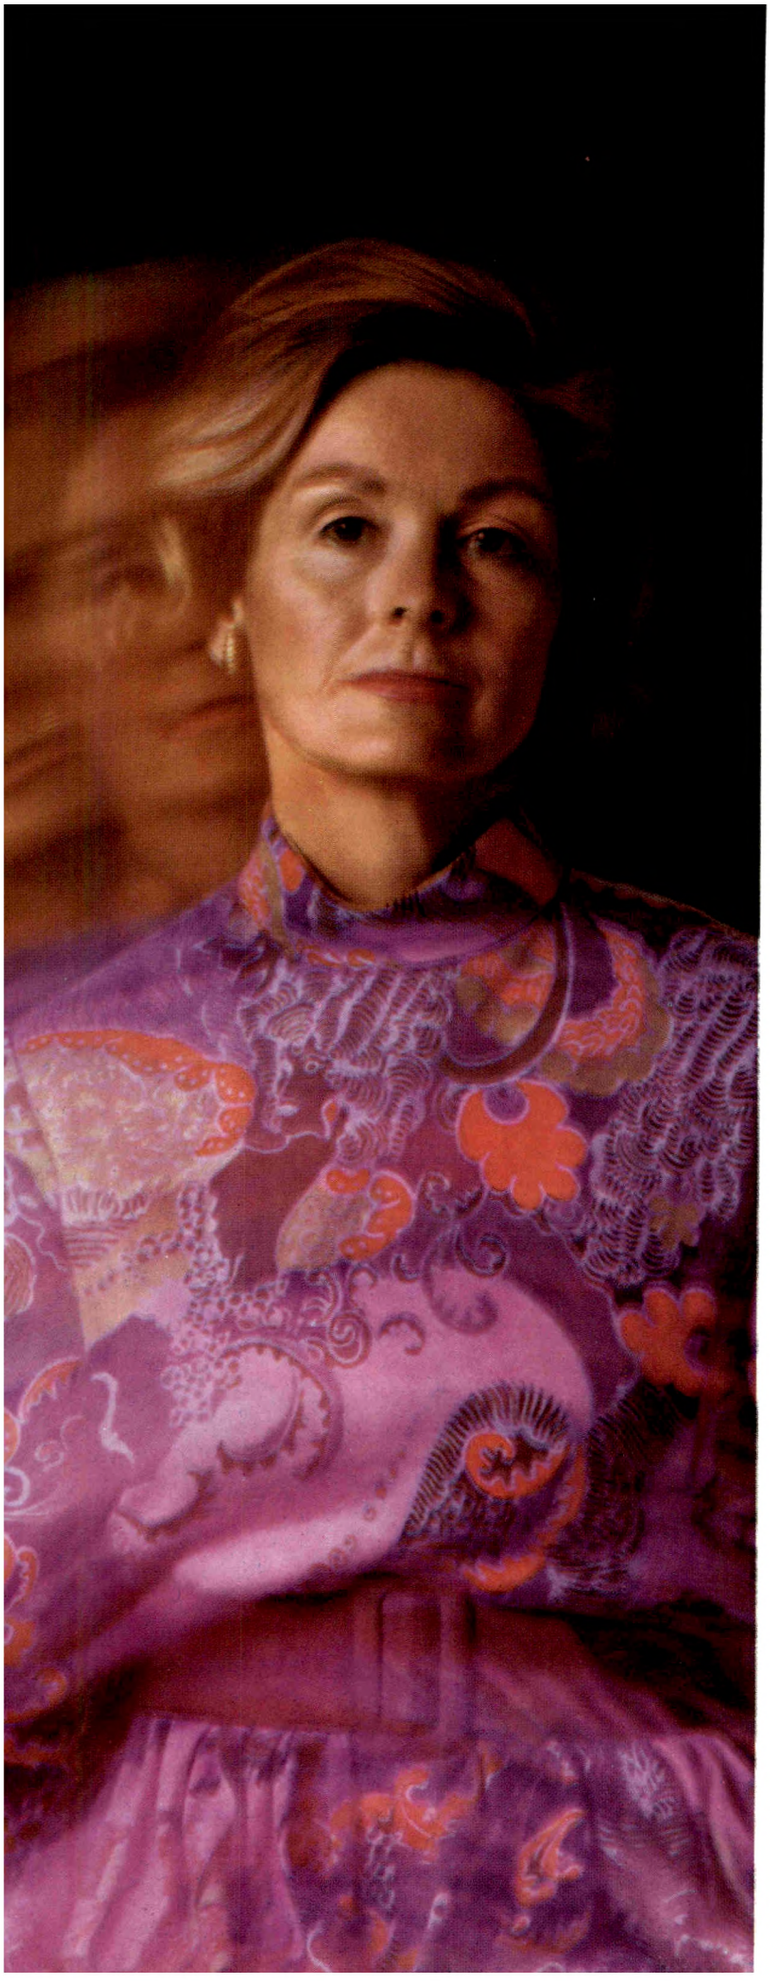
The Genetics of Mental Disorders

ELIOT SLATER and VALERIE COWIE, Queen Mary's Hospital for Children, Carshalton, "The book is beautifully put together, with liberal use of tables, figures, and photographs. ☐ The authors' sophistication and the firm grasp of their field are apparent throughout. . . . Clearly, this book will go a long way toward meeting the need to disseminate such information to all interested readers."—*The Journal of Nervous and Mental Disease*

1971 422 pp. 65 illus. $25.00



Roots of Evaluation



An Epidemiological Basis for Planning Psychiatric Services

J. K. WING and H. HAFNER. ☐ In most countries with extensive health services there is a growing awareness that further development must be based on rational principles and careful planning. This book summarizes research carried out to date, in Europe and the United States, into services for the mentally ill, the intellectually retarded and the elderly mentally ill.

Fall 1973 450 pp. $32.50

OXFORD UNIVERSITY PRESS

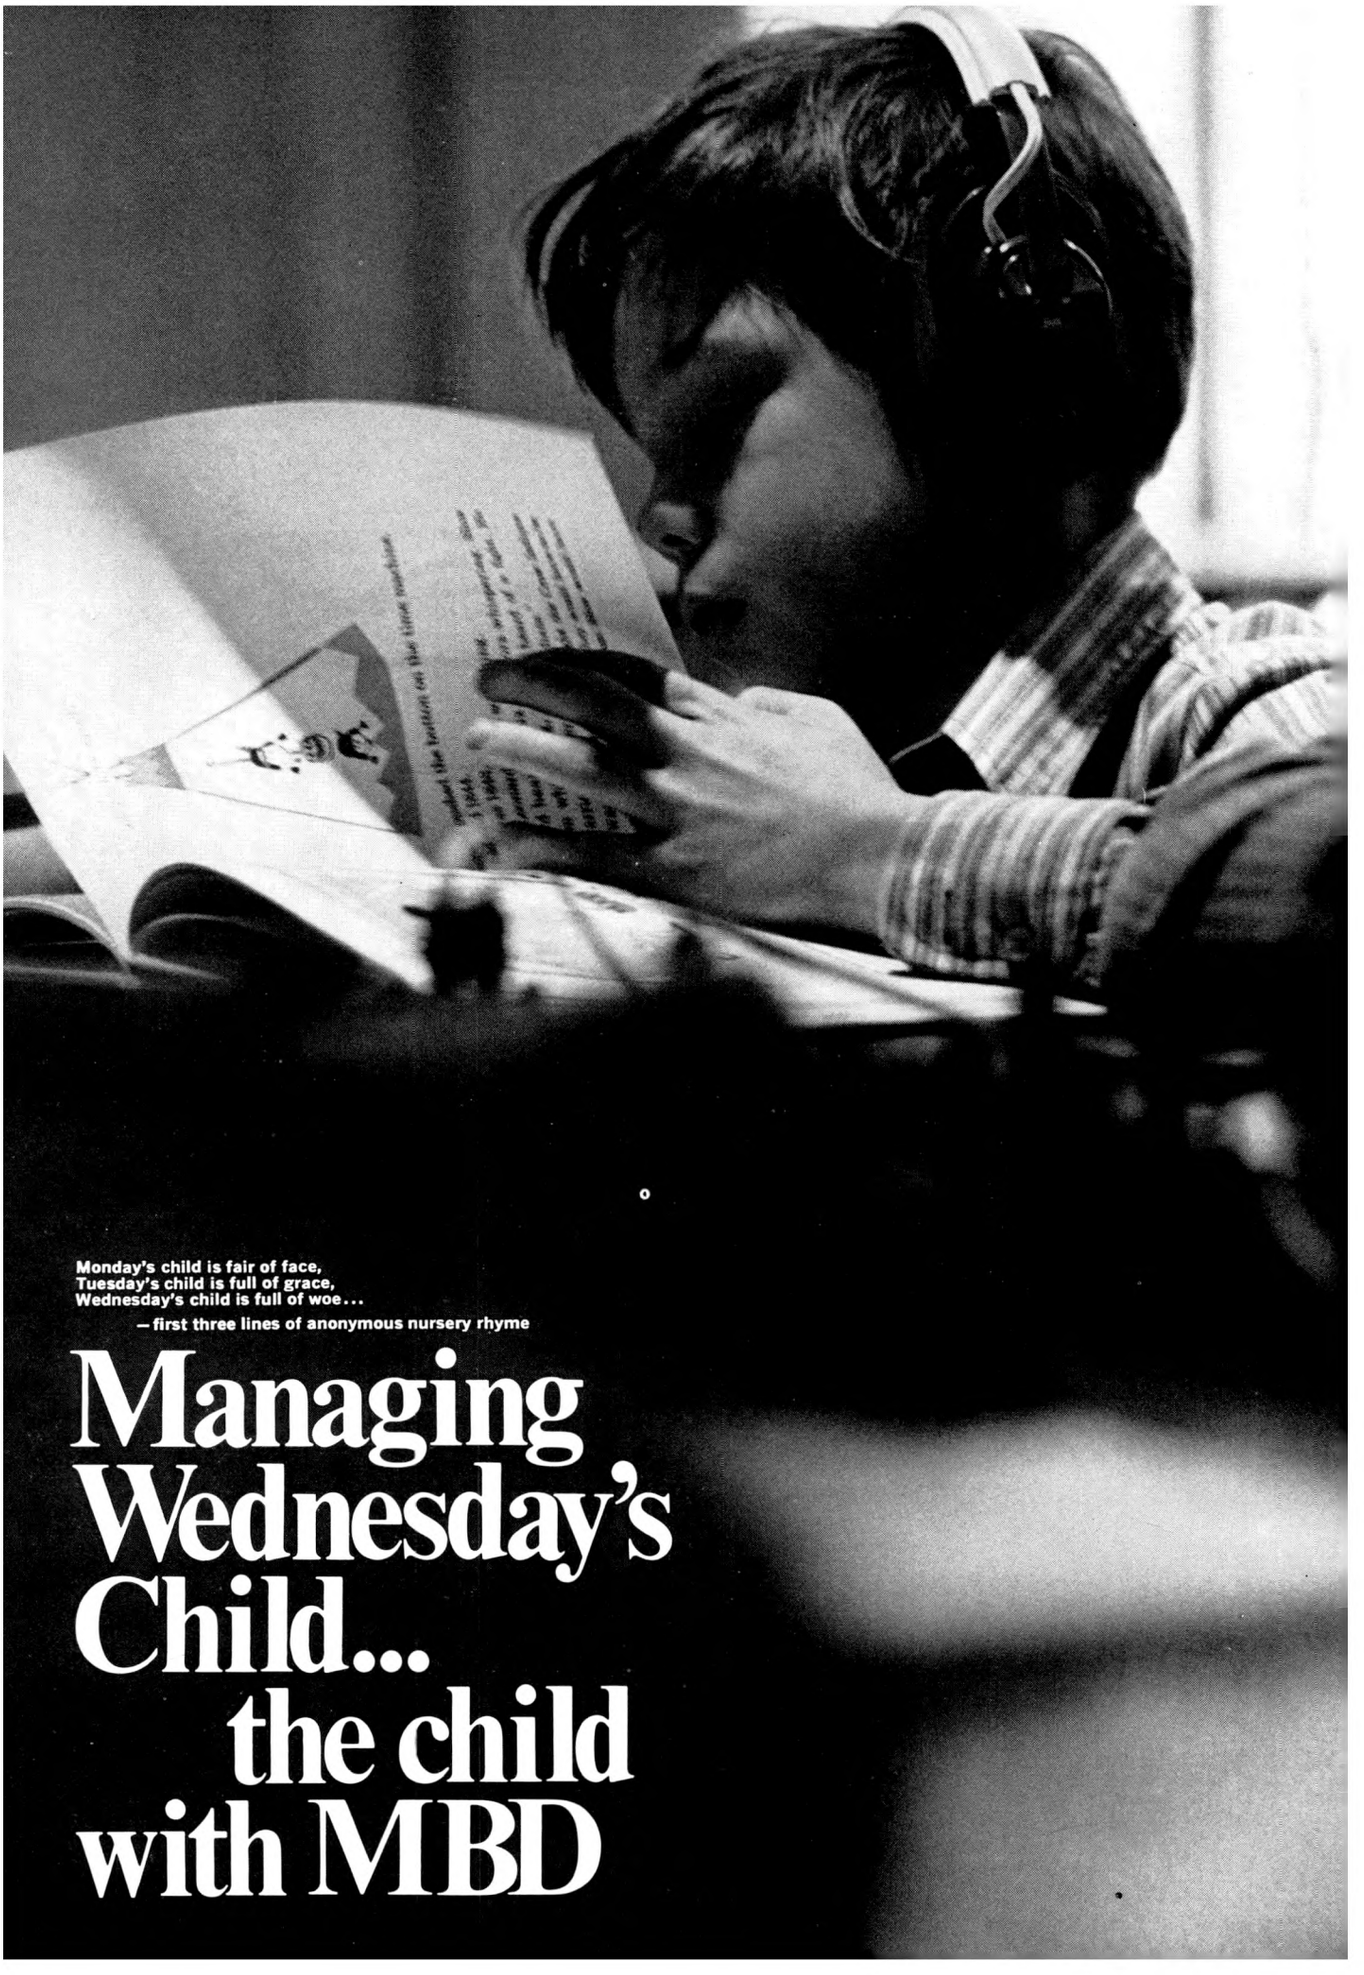
NEW YORK, N.Y. 10016



Focus on rapidity of response...
Antidepressant effect often apparent within 3 to 5 days
Mild accompanying anxiety—as well as psychosomatic complaints and other depressive symptoms—usually disappear as the depression lifts.
Optimal response in most patients with 50 mg. t.i.d. Adolescents and elderly patients often do well on lower dosage.
Pertofrane®
(desipramine hydrochloride NF)
an antidepressant that brings things into focus—promptly
USV
PHARMACEUTICALS

Pertofrane®
(desipramine hydrochloride)

Indication: For relief of mental depression.
Contraindications: Do not use MAO inhibitors concomitantly or within 2 weeks of the use of this drug. Hyperpyretic crises or severe convulsive seizures may occur with such combinations; potentiation of adverse reactions can be serious or even fatal. When substituting Pertofrane in patients receiving an MAO inhibitor, allow an interval of at least 14 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated following recent myocardial infarction and in patients with a known hypersensitivity to tricyclic antidepressants. **Warnings:** Activation of psychosis may occasionally be observed in schizophrenic patients. Due to atropine-like effects and sympathomimetic potentiation, use only with the greatest care in patients with narrow-angle glaucoma or urethral or ureteral spasm. Do not use in patients with the following conditions unless the need outweighs the risk: severe coronary heart disease with EKG abnormalities, progressive heart failure, angina pectoris, paroxysmal tachycardia and active seizure disorder (may lower seizure threshold). This drug may block the action of the antihypertensive, guanethidine, and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery. The concurrent use of other central nervous system drugs or alcohol may potentiate adverse effects. Since many such drugs may be used during surgery, desipramine should be discontinued prior to elective procedures. Caution patients on the possibility of impaired ability to operate a motor vehicle or dangerous machinery. Do not use in women who are or may become pregnant, or in children under 12 years of age, unless the clinical situation warrants the potential risk. Because of increased sensitivity to the drug, use lower than normal dosage in adolescent and geriatric patients. **Precautions:** Potentially suicidal patients require careful supervision and protective measures during therapy. Prescriptions should be limited to small quantities. Discontinuation of the drug may be necessary in the presence of increased agitation and anxiety shifting to hypomanic or manic excitement. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications; transient cardiac arrhythmias have occurred in rare instances. Periodic blood and liver studies should supplement careful clinical observations in all patients undergoing extended courses of therapy. **Adverse Reactions:** The following have been reported: *Nervous System:* dizziness, drowsiness, insomnia, headache, disturbed visual accommodation, tremor, unsteadiness, tinnitus, paresthesias, changes in EEG patterns, epileptiform seizures, mild extrapyramidal activity, falling and neuromuscular incoordination. A confusional state (with such symptoms as hallucinations and disorientation), particularly in older patients and at higher dosage, may require discontinuation of the drug. *Gastrointestinal Tract:* anorexia, dryness of the mouth, nausea, epigastric distress, constipation and diarrhea. *Skin:* skin rashes (including photosensitization), perspiration and flushing sensations. *Liver:* rare cases of transient jaundice (apparently of an obstructive nature) and liver damage. If jaundice or abnormalities in liver function tests occur, discontinue the drug and investigate. *Blood Elements:* bone-marrow depression, agranulocytosis, thrombocytopenia and purpura. If these occur, discontinue the drug. Transient eosinophilia has been observed. *Cardiovascular System:* orthostatic hypotension and tachycardia. Carefully supervise patients requiring concomitant vasodilating therapy, particularly during initial phases. *Genitourinary System:* urinary frequency or retention and impotence. *Endocrine System:* occasional hormonal effects, including gynecomastia, galactorrhea and breast enlargement, and decreased libido and estrogenic effect. *Sensitivity:* urticaria and rare instances of drug fever and cross-sensitivity with imipramine.
Dosage: All patients except geriatric and adolescent: 50 mg. t.i.d. (150 mg. daily). Dosage may be increased up to 200 mg. daily. Geriatric and adolescent patients should usually be started with lower dosage (25 to 50 mg. daily) and may not tolerate higher doses. Dosage may be increased up to 100 mg. daily. Lower maintenance dosages should be continued for at least 2 months after obtaining a satisfactory response. Mild anxiety and agitation which may accompany depression usually remit as the depression responds. Occasionally, however, a sedative or tranquilizer may be indicated. **How Supplied:** 25 mg. capsules (pink) and 50 mg. capsules (maroon and pink), bottles of 100 and 1000; single-dose blister packs, boxes of 500.

USV Pharmaceutical Corp., Tuckahoe, N.Y. 10707

Monday's child is fair of face,
Tuesday's child is full of grace,
Wednesday's child is full of woe...

—first three lines of anonymous nursery rhyme

Managing Wednesday's Child... the child with MBD

"Wednesday's child is full of woe" It need not be this way for the MBD child. He can learn and adjust if given a helping hand.

Without help, the MBD child may be a slow reader, can find writing difficult, and arithmetic hard to grasp. He may be excitable, and his actions can be disruptive. The result can seriously hamper his educational and social development.

But, properly diagnosed and treated, MBD —Minimal Brain Dysfunction—can be brought under control so that the afflicted child can develop normally.

And Ritalin can play an important part in the total rehabilitation program of the MBD child, which includes remedial measures at home and at school. It's currently the drug of choice in many MBD situations.[1]

Ritalin is well tolerated. It can help control the excessive motor activity of the MBD child and ameliorate behavioral and learning problems.

Of course, Ritalin is not indicated for childhood personality and behavioral disorders not associated with MBD.

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

The characteristic signs most often observed are chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; specific learning disabilities; perceptual motor impairment; minor neurological signs and abnormal EEG. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these signs.

Drug treatment is not indicated for all children with MBD. Appropriate educational placement is essential and psychological or social intervention may be necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin is not recommended for children under six years, since safety and efficacy in this age group have not been established.

Since sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available, those requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, and erythema multiforme with histopathological findings of necrotizing vasculitis); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmias; abdominal pain; weight loss during prolonged therapy. In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently. Toxic psychosis has been reported.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Strip Dispensers of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Ritalin®
(methylphenidate)
only when medication is indicated

C I B A

No two depressed patients are exactly alike...

but for many patients with clinically significant depression you'll find a useful dosage form of

ELAVIL®
(AMITRIPTYLINE HCl | MSD)

ELAVIL should not be used during the acute recovery phase following myocardial infarction, in patients hypersensitive to it, or in those who have received an MAOI within two weeks. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Concurrent electroshock therapy may increase hazards associated with such therapy. Patients with cardiovascular disorders should be watched closely. The drug may impair mental or physical abilities required in hazardous tasks and may potentiate the effects of alcohol.

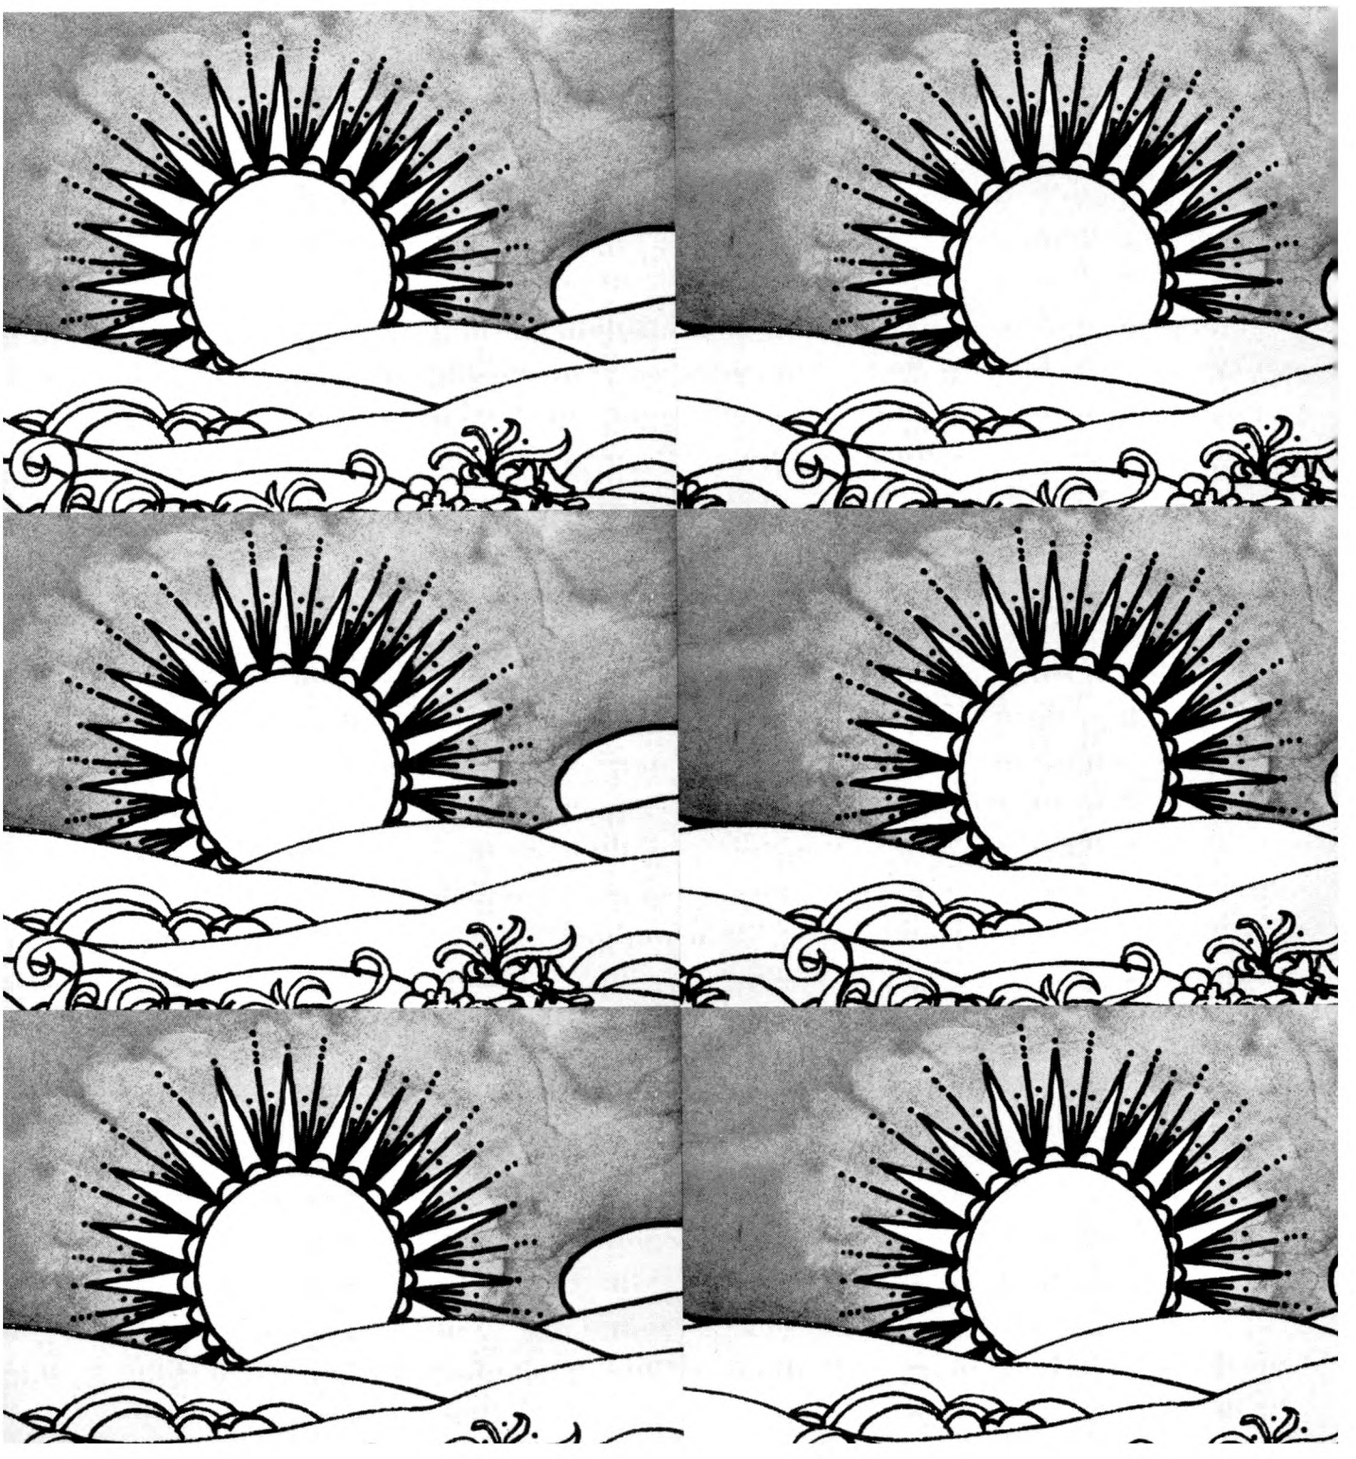
Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia, and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have easy access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.



Overdosage: The intravenous administration of 1–3 mg of physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

ıblets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

blets and Elixir Indications: FDA has evaluated this drug as Effec- e as an adjunct in the therapy of the indications listed below der SEQUELS.

INDICATIONS FOR ARTANE SEQUELS:
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/ or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms f parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine nd phenothiazines.

RNING:
ents to be treated should have a gonioscope evaluation and e monitoring of intraocular pressures at regular periodic intervals.

autions: Patients with cardiac, liver or kidney disorders or with rtension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.

Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

drug in sustained release form has been evaluated as probably effective. See Brief Summary.

First day in the hospital and all efforts will be directed toward returning her to the community.

For psychotic patients with mixed anxiety-depression, Mellaril has been found useful to help patients participate more fully in the entire therapeutic program. Continued medication with Mellaril is often basic to helping patients prepare for and participate in outpatient treatment programs that bridge the gap between hospital and community.

With Mellaril, patients are generally alert and in better contact with reality and can more fully benefit from the entire therapeutic program. (In the hospital or out, even though Mellaril produces only minimal sedative effect, patients should be warned about participating in activities which require complete mental alertness, e.g., driving.) And, although extrapyramidal symptoms are characteristic of this class of drug, a distinctive feature of Mellaril is that extrapyramidal stimulation —notably pseudoparkinsonism—is minimal.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg., 50 mg., 100 mg., 150 mg., and 200 mg. thioridazine HCl, U.S.P.

helps in the management of psychotic patients with mixed anxiety-depression

A34

Before prescribing or administering, see Sandoz literature for full prod information. The following is a brief summary.

Contraindications: Severe central nervous system depressio comatose states from any cause, hypertensive or hypotensive he disease of extreme degree.

Warnings: Administer cautiously to patients who have previou exhibited a hypersensitivity reaction (e.g., blood dyscrasias, ja dice) to phenothiazines. Phenothiazines are capable of potentiat central nervous system depressants (e.g., anesthetics, opiates, cohol, etc.) as well as atropine and phosphorus insecticides. D ing pregnancy, administer only when the potential benefits exce the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukope and/or agranulocytosis and convulsive seizures. In epileptic tients, anticonvulsant medication should also be maintained. F mentary retinopathy may be avoided by remaining within the r ommended limits of dosage. Administer cautiously to patients p ticipating in activities requiring complete mental alertness (e. driving), and increase dosage gradually. Orthostatic hypotens is more common in females than in males. Do not use epinephr in treating drug-induced hypotension since phenothiazines may duce a reversed epinephrine effect on occasion. Daily doses excess of 300 mg. should be used only in severe neuropsychiat conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especia with large doses, early in treatment; infrequently, pseudopark sonism and other extrapyramidal symptoms; nocturnal confusio hyperactivity, lethargy, psychotic reactions, restlessness, and hea ache. *Autonomic Nervous System*—Dryness of mouth, blurred sion, constipation, nausea, vomiting, diarrhea, nasal stuffine and pallor. *Endocrine System*—Galactorrhea, breast engorgeme amenorrhea, inhibition of ejaculation, and peripheral edema. *Ski* Dermatitis and skin eruptions of the urticarial type, photosen tivity. *Cardiovascular System*—ECG changes (see *Cardiovascular fects* below). *Other*—A single case described as parotid swelling. The following reactions have occurred with phenothiazines a should be considered: *Autonomic Reactions*—Miosis, obstipatio anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfol tive dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulo tosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplas anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal eden angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, bilia stasis. *Cardiovascular Effects*—Changes in terminal portion of ele trocardiogram, including prolongation of Q-T interval, loweri and inversion of T-wave, and appearance of a wave tentative identified as a bifid T or a U wave have been observed with pher thiazines, including Mellaril (thioridazine); these appear to be versible and due to altered repolarization, not myocardial damag While there is no evidence of a causal relationship between the changes and significant disturbance of cardiac rhythm, seve sudden and unexpected deaths apparently due to cardiac arre have occurred in patients showing characteristic electrocard graphic changes while taking the drug. While proposed, perio electrocardiograms are not regarded as predictive. Hypotensio rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akat sia, agitation, motor restlessness, dystonic reactions, trism torticollis, opisthotonus, oculogyric crises, tremor, muscular ri ity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent sometimes irreversible tardive dyskinesia, characterized by rh mical involuntary movements of the tongue, face, mouth, or (e.g., protrusion of tongue, puffing of cheeks, puckering of mo chewing movements) and sometimes of extremities may occu long-term therapy or after discontinuation of therapy, the ris ing greater in elderly patients on high-dose therapy, espe females; if symptoms appear, discontinue all antipsychotic ag Syndrome may be masked if treatment is reinstituted, dosa increased, or antipsychotic agent is switched. Fine verm movements of tongue may be an early sign, and syndrom not develop if medication is stopped at that time. *Endocri turbances*—Menstrual irregularities, altered libido, gynecor lactation, weight gain, edema, false positive pregnancy *Urinary Disturbances*—Retention, incontinence. *Others*—H rexia; behavioral effects suggestive of a paradoxical reac cluding excitement, bizarre dreams, aggravation of psycho toxic confusional states; following long-term treatment, a skin-eye syndrome marked by progressive pigmentation or conjunctiva and/or accompanied by discoloration exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

Community Mental Health Services in Britain

BY DOUGLAS BENNETT, M.D., D.P.M.

Although the practice of psychiatry was similar in the United States and Britain during the last century, since then their paths have diverged, especially since the Second World War and the institution in Britain of the National Health Service. The major postwar development in Britain has been in social psychiatry, with particular reference to hospitalized psychotic patients. More recently, plans have been made to close mental hospitals and shift the locus of inpatient care to the general hospital. Projections have been made to provide services on a sector basis, in which teams of psychiatrists, nurses, and social workers serve population groups of 60,000 each and provide outpatient and transitional facilities as well as inpatient care. The author compares the different approaches in the United States and Britain and notes that, while neither can provide an ideal service, both can learn much from the differences.

WHEN WE IN BRITAIN use the word "community" in a mental health context, we are referring to care given outside the mental hospital in the mythical world of well people (1). We may include, too, the prevention of hospital admission and the idea of district or sectorized care. In the United States, "community" in a mental health context seems to have more to do with localism and the idea that services are better managed at the community level. I have heard it suggested that this view, which may have been inherited from Utopian thinkers of the 18th century, now reflects a dislike of the direct provision of services by the state (2). Whether that is so or not, it does emphasize the fact that since "community mental health" is deeply rooted in the history and the beliefs of our respective societies, it also has different meanings for both of us.

In trying to explain something of community mental health in my country I must try to make these differences clear. But I shall also try to avoid dangerous comparisons, for in the worldly wisdom of Samuel Johnson, "by exciting emulation and comparisons of superiority, you lay the foundations of lasting mischief; you make brothers and sisters hate each other." That I do not want to do.

Read as a special lecture at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Bennett is Psychiatrist, the Bethlem Royal Hospital and the Maudsley Hospital, Denmark Hill, London SE5 8AZ, England.

OUR INHERITANCE

In the 19th century the practice and problems of psychiatry were very similar in our two countries. We both had our reformers. You had Dorothea Dix, who believed in the value of the mental hospital. We had John Conolly, who, by abolishing physical restraint, did much to improve our care of the mentally ill. Many before him had thought that the physical restraint of the mentally disordered could and should be reduced, but no one thought that it was possible to abolish it completely (3). Conolly's action in doing this led to great controversy, for he was eager that the mentally ill should be treated with the same good intentions as doctors treated the physically sick. Whatever we think now about equating mental disorder with illness, at that time it did much to better the social position and to increase the freedom of the mentally sick. So it is not surprising that Conolly also believed that mental disorders should be treated, whenever possible, outside the mental hospital. It took some time for his ideas to be accepted and their full impact had to wait on later social changes; I cannot tell the whole story.

In the latter part of the last century and in the first half of this one, matters moved forward rather sedately. Then the shared dangers and experiences of the Second World War drew people of all classes in our society closer together. By the end of the war it was accepted that it was the proper function of government to ward off stress and strain not only among the poor but among all classes of society. Sir William Beveridge's plan to combat the evils of want, disease, ignorance, squalor, and idleness was implemented in a series of enactments that led to what we now call the Welfare State. In an attempt to deal with

disease, the National Health Service was established as one limb of this body.

Some see our Welfare State as helping the disadvantaged to make good; others see it as undermining people's self-sufficiency by state handouts. But whatever one's opinion of its effect on the wider society, its egalitarian philosophy of "bread for all before cake for anybody" has had a very considerable influence on the provision of services for the mentally ill. In the National Health Service, which came into being in 1948, psychiatrists (like other doctors) were salaried. They received the same pay as the surgeons and internists wherever they worked. The service brought all the hospitals, whether general or mental, formerly managed by local bodies, under the same regional and national direction. As soon as these hospitals were administered side by side the difference in the quality of care given to the mentally disordered and the physically ill was shown up in bold relief. Also, the difference in the terms under which people were eligible for treatment was so great that quite soon the whole question of legal commitment was referred to a Royal Commission (4).

Their enquiry and recommendations led to a new Mental Health Act, which was passed by Parliament in 1959. This act made it possible for the mentally ill person who could accept the role of patient to be admitted to a hospital without the formality of commitment. Committal, when needed, was no longer a quasijudicial process. Instead, two doctors, one a qualified psychiatrist, had to explain why care or treatment was needed and why the individual could not be treated in the role of a voluntary patient. Today less than 17 percent of admissions to our psychiatric hospitals are compulsorily committed, and only six percent of hospital residents are detained in this way. The Royal Commission also stated the view that greater efforts should be made to avoid hospital admissions. Its report gave official recognition to those community psychiatric services which had already been developed up and down the country and encouraged a further use of out-of-hospital care.

PRESENT THINKING

In the words of one American visitor: "The major postwar development in British psychiatry has been in social psychiatry, with particular reference to psychotic patients in hospital. By contrast, in the United States, a major development has been in so-called dynamic psychiatry, with particular reference to ambulatory neurotic patients" (5). Knight Aldrich thought, quite rightly, that our pattern of care was a direct outcome of the National Health Service, an origin that has influenced its subsequent development.

Since both the mental hospitals and the general hospitals are managed by the same regional hospital boards, the planning of community psychiatry services has been undertaken in a medical context. This was Ministry of Health policy, and in 1960 its Chief Medical Officer, Sir George Godber, urged that "if the opportunity for bringing psychiatry fully into the general pattern of medicine which now presents itself is grasped, the new attitudes created both within the profession and in the public mind, will do more for mental health than any other single measure" (6).

At that time the Ministry of Health was encouraging the development of psychiatric outpatient, day-patient, and inpatient services in general hospitals but still thought that a substantial part of hospital psychiatric work would have to be undertaken in the traditional mental hospital. More recently the department has decided that improvements in treatment and care allow us to replace the large separate mental hospitals with a service based in the general hospitals. This is a dramatic change in policy. In such a service the general hospital psychiatric unit will combine with the other two parts of our three-part health service—that is, the family doctor and public health sectors—to provide comprehensive psychiatric care to a defined district. The Department of Health intends that these facilities should be used as flexibly as possible and that emphasis should be given to rehabilitation and to the preservation of continuity in the patient's personal relationships and his contacts with his local community (7). There are hopes that these three parts of the medical services can plan more effective comprehensive care when, next year, they are merged and administered by area health boards.

This is the rhetoric; you may wonder by how much it is separated from reality. There is of course a gap, but it may be narrowing rather than widening. It should be filled in part by a newcomer to our services: the social services department of the local authority. This new body grew out of the appreciation by the social workers and government that the existing social services were responsible only for certain types of social problems and the difficulties of particular age groups (8). It was felt that human needs could not be categorized in such an arbitrary fashion in spite of the realization that medical care, education, and housing all have social components. So it was decided that social workers should give up such former specialisms as mental health, child care, and welfare and merge these into one department providing a unified family service. Social workers accepted this, integrated their professional associations and their differing trainings, and, when sanctioned by the Social Services Act of 1971, took charge of their own departments in the local authorities.

While some people regret the disappearance of the former mental health and psychiatric social workers, the new departments provide a useful social counterpoise to our medically oriented psychiatric services. But the departments are young and are preoccupied with their own internal problems, so it will be some time before the social workers can make their full contribution to community mental health. Meanwhile, many psychiatrists say that the removal of social workers from the medical orbit has made effective cooperation impossible (9). Since there are plenty of examples of fruitful cooperation between psychiatrists and social service departments, these remarks only show that many doctors do not know how

to work for and with social workers. The doctor's outlook has some importance, for the next stage of our planned development is the closing of the mental hospital, and that requires teams of social workers, psychiatrists, and others to work together to meet the needs of a specified population. The administrative discontinuity between health and social service departments must make teamwork difficult, although with the right attitudes this could be overcome.

CLOSING THE MENTAL HOSPITAL

The arguments for closing the mental hospital have never been very clearly stated. In the 1950s community care was seen as preventing admission, or, failing that, securing the patients' early discharge from the hospital. Such a policy was community minded only in the sense that it was anti-institutional. Not surprisingly, a comparative evaluation of three dissimilar services, including a community service with a worldwide reputation, did not confirm the value of this limited type of community care (10). In spite of this as well as great and well-known achievements of some of our mental hospitals, they have remained the villain of the piece in community mental health. Many people feel that the continuing accumulation of patients in these ghettos has cast a shadow over all our services and mocks our therapeutic pretensions.

Some argue that we cannot get rid of our mental hospitals before we have adequate alternative services. Certainly we have an increasingly clear idea, in numerical and other terms, of the alternatives that are needed (11). Others believe that alternative services will not be provided as long as the mental hospital remains as a convenient way to dispose of difficult problems.

We know that as long as we have mental hospitals we are unlikely to prevent admission to them. Hopes that this would happen have always overlooked one important aspect of psychiatric care: the desire of mental health professionals to get rid of undesirable patients. This distinction is almost unique to psychiatry and reflects an intolerance rooted in the inability of doctors and others to deal with their own feelings, whether of hostility, anxiety, or a sense of failure (12).

There are many ways of tackling the problem, but the fundamental solution is that professional staff members have to give up the right to refuse referrals and the right to refuse to refer people to other services (13). In practice, undesirable patients are referred in only one direction, whose final destination is the mental hospital. Elimination of the mental hospital does not solve the problem entirely, for with or without the mental hospital, both doctors and social workers may refer unwanted patients to colleagues with lower status or less training (14). But the taking apart of mental hospitals will force the staff to look for other solutions and to rethink the real nature of psychiatric care.

Part of the hospital dismantling happens naturally, for in our country, as in yours, there is a steady attrition of long-stay hospital patients by discharge or death and only a slow accumulation of new chronic patients (15). Simultaneously, new patients have to be diverted to other services and in particular to the district general hospital. There are dangers for the mental hospital. The knowledge that the hospital is going to close can lead to a sharp decline in staff morale, which results in a deterioration in standards of care. To avoid this it is proposed that the mental hospital's catchment area should be split into geographical districts of 60,000 population. Then each district will be served by a team made up of district general hospital and mental hospital staff members and social workers from the new departments. The beds and day places in both the mental hospital and the district general hospital will be divided, so that each team has day places and beds in both situations (7). When eventually the new general hospital psychiatric department can provide all the necessary services, the few patients remaining in the mental hospital will be transferred to another mental hospital whose closure program is less advanced. This is an ambitious plan and progress must be slow, for evolution, not revolution, is the aim. Even so, reaction—especially from doctors—has been quite brisk.

DOUBTS AND DIFFICULTIES

In such a situation reality and rhetoric tend to drift apart. I have already introduced you to what Titmuss (16) called "that exotic hothouse climbing rose, 'the welfare state,' with its lovely hues of tender pink and blushing red, rampant and rampaging all over the place, often preventing people from 'standing on their own feet,' in their own gardens." He went on to wonder whether the everlasting cottage garden trailer "community care" did or did not conjure up a sense of warmth and human kindness essentially personal and comforting. It may have done so, but it has conjured up controversy and criticism too. Doctors hold strongly partisan views for or against community psychiatry; these have been thought to have a distinctly American flavor (17). But these views are equally evident in Britain. I suspect that the flavor is neither British nor American, but medical.

The public, on the other hand, seems to welcome the community approach. They have always cared for the mentally ill, and it is only in quite recent years that they have begun to trust the mental hospitals to do this for them. Of course the mentally ill were not always well cared for outside the hospital. However, a national opinion poll in 1971 showed strong public support for undertaking the care of the mentally ill in the community (18). Six out of every ten people interviewed thought that the mentally ill should be encouraged to lead a normal life. At the same time, the public openly discusses and criticizes conditions in mental hospitals that previously were not mentioned in the press (19). Meanwhile some psychiatrists, seemingly forgetful of recent scandals, revive nostalgic memories of mental hospital gardens with their flowers and green lawns and speak of them as a sanctuary for patients (20).

While the debate continues, community psychiatry has

not provided a ready banner for those in our islands demanding social change or marching in a radical activist cause (21).

More substantial doubts have been expressed about the government's plans. The statistical projections of change in bed needs and the experiences of a few community services are critically questioned, for it is on these rather doubtful data that the plan seems to be based (22–24). The success of the plan in its present form depends on certain assumptions "which have not yet been tested; that very few patients will in future become severely handicapped psychiatrically, that those who do so will either not require residential care or can be looked after adequately by the social services and that the disadvantages apparently inherent in the mental hospital system will not be inherent in any system which replaces it" (11).

It does seem that the number of hospital beds allowed in the plan may be too low. It seems, too, that little or no thought has been given to the needs of that small number of patients, mostly with schizophrenia or organic mental syndromes, who still become handicapped in spite of all we do. Obviously there will be difficulties in establishing effective cooperation between psychiatric units in the district general hospitals and the new social service departments that, between them, will have to provide the shelter and the rehabilitation services that were the mental hospitals' special contribution to the care of chronic patients. There are doubts, too, not only about how they will cooperate, but how each will meet its own responsibility. Some wonder whether the social service departments can provide these facilities, or whether they can provide them in time.

It is important that the provision should be kept in phase with the transfer of medical services from the mental hospital to the district general hospital. Doctors doubt whether the general hospital, for its part, can cope with patients whose problems are difficult or chronic. It is assumed that because general hospitals have dealt only with the less severely ill, that is all they can do. This is not so, but of course they will have to change their ways of functioning and they will need support from other services as well as accommodation in hostels, boarding houses, and day centers for those with permanent handicaps.

THE PRESENT SITUATION

It is unlikely that the scheme in its present form will meet all these needs, and evaluation of the services is essential. There is ongoing evaluation of some developing services, and other evaluations are projected (11). The findings, taken together with the experience of clinicians, should lead to later modifications of the government's policy.

It will be clear from this account that our present mental health services are still largely centered on the hospital and the psychiatrist. Our major aims are the prevention of chronic patienthood and the closing of the mental hospital, rather than primary prevention, consultation, and crisis intervention. This outlook is in part an expression of our pragmatism and in part determined by the history and the logic of our situation. Having recognized that with the means at our disposal we could not prevent mental illness or prevent some patients from developing very severe handicaps, we decided that we would deal with what was within reach not only of our understanding but of our resources. In time we shall do more for mental health than for mental illness and be more interested in communities than hospitals. At present, manpower is limited and so are budgets; this has an effect on what is done.

There will be three psychiatrists (and only one of those a senior) for the population of 60,000 persons that is the basic unit in our planning. This population will yield about 500 patients who are in our care at any one time while approximately another 500 people, 215 of them inpatients and about 265 outpatients, will come into care each year (25). They will be supported by hospital and public health nurses and by social workers. There will also be about 24 family doctors in the area. These doctors, however, cannot give psychiatrists much help, for in our health service family doctors are already seeing the bulk of the patients with socio-emotional problems (26). These patients suffer mostly from minor affective illnesses that are associated with various forms of social difficulty (27). The family doctor's interest in his patients' socio-emotional difficulties and his capacity to deal with them are closely related, whether by cause or effect, to the size of his practice (28). He refers those with the more difficult and time-consuming problems to the psychiatric outpatient departments and is often reluctant to support them after they are discharged from the hospital. Many solutions have been proposed: these include giving family doctors more education and understanding of socio-emotional problems and reorganizing their practices on a group basis with social workers attached. While matters are slowly changing, we know that many family doctors are still not keen on working with social workers (29).

When people suggest, as many do, that we cannot meet the requirements of a community-based mental health service with our present resources, they overlook the fact that the redeployment of these resources, if it does not improve the situation greatly, is unlikely to worsen it. Staff morale can have a considerable effect, and it seems clear that the morale of mental health personnel is higher when they work outside mental hospitals. At the same time we are uneasily aware of the increasing demand on services that are separate from mental hospitals. Also, the scope of psychiatry's responsibilities is more broadly defined. It is no longer enough to provide for the needs of the mentally ill, the mentally retarded, and disturbed children. We have to provide more service for mentally disturbed offenders, mentally infirm old people, alcoholics, drug addicts, and those who attempt suicide and self-poisoning.

It seems obvious that if we are to meet all these new demands, our tasks and responsibilities will have to be reallocated. A service based on sectorized care has certain advantages in this respect, for the sector defines the responsibility of psychiatrists and others who have to

share the patients' care. It forms a base for cooperation with families and with a range of services providing social help whose very existence is undreamed of by many hospital psychiatrists. Even today, district services have provided some working or living environments for those persons who are severely handicapped by mental illness and who lack family support. There are not enough, but they are there and provision for them is growing. Of course, sectorization does not ensure that the psychiatric and social services will cooperate. So much has been said and written about continuity of care, cooperation, coordination, and teamwork that the words have all but lost their meaning. They do not tell us how to work or what to do. They provide no basis for teaching psychiatrists. Many still think that community psychiatry is nothing more than keeping the patient out of the mental hospital, giving first aid care, talking to a social worker, or sending the patient to a day hospital. Some believe that community services allow psychiatrists to escape the painful business of facing up to the patient's problems. Nothing could be farther from the truth.

THEORY AND RESEARCH

There is much more to community mental health services than their administrative structure. It takes more than goodwill, common sense, and enthusiasm to provide effective help. Meyer Gross said many years ago that "advances in mental health are not made by administrative dodges or by giving new names to old problems." Some old problems are always with us, and none is more teasing than the balance of advantage and disadvantage between treatment in the hospital or in the community. There is no right or wrong solution, only better or worse decisions for certain people, at certain times, and in certain circumstances. Yet we cannot learn how to make those decisions, modify our services, or teach others unless we have a sound basis in theory and research. While community psychiatry must have a practical base in a sectorized service, its theoretical foundation is in social psychiatry. Sabshin brought these two facets together when he said that community psychiatry uses social psychiatry's techniques, theories, and methods, as well as those of the other behavioral sciences to meet the mental health needs of a defined population over a significant period of time (17).

It is one of the little-known strengths of the British community mental health service that we have a small but influential group of research workers in social psychiatry. Their work grew out of the Medical Research Council's Social Psychiatry Research Unit, which was founded by Sir Aubrey Lewis in 1948—the same year that the National Health Service was established. Their research and their names are well known (30). They have influenced plans and policies and have provided guidelines in matters of patient management, rehabilitation, and social treatment.

It is still difficult to attract first-class clinicians from the hospital to community mental health. The view that they will come to us only when they see that community mental health has scientific substance is reflected in the remarks made by a young American lecturer working with us. "It is this emphasis on the scientific validation of delivery systems and treatment techniques which lends respectability to the movement and makes community psychiatry a proper pursuit within the university" (31). But trainees must not learn only about community and social psychiatry. They have to learn to be community psychiatrists. Training in community psychiatry requires that the student work in a situation where the patient and his family remain the staff's responsibility over a considerable period of time. The community psychiatrist does not learn by working in private with highly selected patients who are "his" alone. He has to learn through the sobering experience of sharing with a team the care of those who may be poor, unintelligent, or poorly motivated or who may fail to improve with treatment (32). The knowledge that there is no escape from this responsibility and that the team's failure to help the patient involves them in his long-term care concentrates the mind wonderfully and leads to more ingenious and useful solutions. The resulting growth of staff confidence and competence is another factor that is rarely taken into account yet is crucial to the future function of our community mental health services.

In Britain, at least, community psychiatry is not a soft option, offering "less painful jobs at higher salaries, with high sounding titles, plus opportunities for community contact, the novelty of newspaper interviews and speech making" (33). I doubt whether it is like that in America either. For wherever we work, our methods differ and our failings and our excellences differ. Neither of our two countries can provide the ideal service. One hopes that we can learn something from our differences.

Questions of the Month

Directions: Each of the incomplete statements below is followed by four or five completions. Select the *one* that is BEST in each case.

Question 1 The sudden and repeated cessation of a person's train of thought or speech in the middle of a sentence (blocking) is most characteristic of
(A) children in latency (7–11 years)
(B) psychotically depressed patients
(C) schizophrenic patients
(D) patients with Korsakov's disease
(E) patients with manic-depressive psychosis

Question 2 Myoclonic jerks or generalized convulsions with paroxysmal activity on the electroencephalogram may be observed prior to drug withdrawal when high daily dose levels have been attained during chronic intoxication with
(A) heroin
(B) methadone
(C) cocaine
(D) pentobarbitol (Nembutal)
(E) meperidine (Demerol)

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are supplied on page 1081. The references for the questions are supplied on page 1117.)

Epidemiological Differences Between White and Nonwhite Suicide Attempters

BY ANDREAS M. PEDERSON, PH.D., GEORGE A. AWAD, M.D., AND ALAN R. KINDLER, M.B.B.S.

Using the Monroe County (N.Y.) Psychiatric Case Register, a stable data source, the authors attempted to determine differences between white and nonwhite suicide attempters, to identify the factors that are associated with self-destructive behavior in both groups, and to determine the subsequent mortality rate among suicide attempters. They found a number of differences between whites and nonwhites and conclude that the motivation for suicide, the techniques used to treat attempts, and the degree of risk of further psychiatric difficulty may be different for the two groups.

DURING THE PAST SEVERAL YEARS an increasing amount of research on suicide and suicide attempts has been conducted (1). Many of these studies have focused on the relationship between suicide and suicide attempts (2, 3), while others have focused on the clinical course and outcome of persons who have attempted suicide (4). A number of these studies have outlined basic demographic characteristics and some psychological factors associated with people who attempt suicide; however, the epidemiological study of suicide attempts is one major area of investigation that has only recently begun to be examined systematically (5).

Although our knowledge about suicide attempts has increased considerably, a number of questions about the factors associated with persons who attempt suicide remain unanswered. Part of this is due to the unreliable data collection systems that are used to record attempted and accomplished suicides in most communities. Another problem is that many of the previous studies on suicide attempts have used relatively small or highly selected samples. For example, most have included only those suicide attempts which have been identified by admission to general hospitals or by reports to the police. Because of the variability in data collection systems and because different sample selection procedures have been used, conclusions based on comparisons of these studies are of limited validity.

Further, while there is evidence to suggest that patterns of suicide attempts and characteristics of attempters are different in white and nonwhite populations (6, 7), little work has been done to investigate these differences in a systematic manner. These differences could produce considerable variance in studies of attempted suicides, particularly with certain types of sample selection procedures. More importantly, however, if race is not examined as a separate factor, true differences between white and nonwhite groups, which may indeed be helpful in understanding attempted suicides, may go unnoticed.

We attempt in this paper to clarify some of the problems found in previous research through an epidemiological study of suicide attempts in a relatively stable population over a four-year period. By examining the differences between white and nonwhite suicide attempters and outlining the demographic characteristics of suicide attempters, we hope to identify the characteristics associated with high-risk groups in terms of self-destructive behavior and to provide some insight into the underlying motivations for a wide range of self-destructive and potentially suicidal behavior. In addition, we will investigate the number of deaths among these suicide attempters in a five-year follow-up period, looking particularly at those deaths attributed to suicide.

METHOD

The sample consists of all consecutive suicide attempters treated in the emergency department of Strong Memorial Hospital during the years 1964 through 1967. Strong Memorial Hospital, the teaching hospital of the University of Rochester School of Medicine and Dentistry, is the largest general hospital in Monroe County, New York. During this study period the average yearly number of patient contacts in the emergency department was about 55,000. Every suicide attempter or suspected attempter who was treated in the emergency department was seen by a psychiatric resident before discharge. This contact was then reported to the Monroe County Psychiatric Case Register.

The Monroe County Psychiatric Case Register was used to identify the characteristics of the suicide attempters seen during the study period. The register was started on January 1, 1960, and nearly every psychiatric contact made in Monroe County has been reported to it since

At the time this work was done, the authors were with the Department of Psychiatry, University of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd., Rochester, N.Y. 14642, where Dr. Pederson is Assistant Professor of Psychiatry and Psychology and Drs. Awad and Kindler were residents in psychiatry. Dr. Awad is now Associate, the Clarke Institute of Psychiatry and the Psychiatric Service of the Provincial Court (Family Division), Toronto, Ont., Canada, and Dr. Kindler is Associate, Department of Psychiatry, University of Toronto.

The Monroe County Psychiatric Case Register was supported from 1960 to 1969 by Public Health Service grant MH-00381 from the National Institute of Mental Health and is currently supported by the New York State Department of Mental Hygiene, the Monroe County (New York) Board of Mental Health, and the University of Rochester. This work was supported in part by these funds and by Public Health Service grant MH-08469 from NIMH.

then (8). In addition to basic demographic data about each patient, diagnoses, including the designation "suicide attempt," are recorded for each psychiatric contact, along with an indication of the presence or absence of previous psychiatric care. The register also records the deaths and their causes for every person who has been reported. This procedure creates not only a continuing psychiatric register but also a continuing and updated death register. In the register, race is categorized as white or nonwhite. The white group includes all Caucasians and most of the Puerto Rican and American Indian ethnic groups, while the nonwhite group is composed almost exclusively of people of Negroid ancestry. The socioeconomic level of a person who is reported to the register is defined by the census tract in which he lives. Each census tract in Monroe County has been classified into one of five groups (from I at the highest to V at the lowest) on the basis of a composite index of social and economic factors. These factors and the method of classification have been described elsewhere (9).

Out of 219,233 emergency room contacts at Strong Memorial Hospital during the study period (1964 through 1967), 1,345 persons were seen as the result of a suicide attempt. While there were five other hospitals with emergency services in the Rochester-Monroe County area during the study period, Strong Memorial Hospital had nearly twice as many emergency room contacts per year as any other, and it was the only hospital that had a psychiatric facility in the emergency department. Because of its range of services and psychiatric facilities, most suicide attempts in the county area were referred to Strong Memorial Hospital. Examination of the emergency log from another large general hospital, which ranked third in the number (121, 266) of total emergency room contacts during the study period, revealed that only 125 suicide attempts had been treated in its emergency department.

Unlike samples used in many other studies of suicide attempts, this sample has the advantage of including all consecutive suicide attempts seen in an emergency department; it consequently provides a wider range of suicidal behaviors, from the mild suicide gesture to the relatively serious attempt. Also, because most of the suicide attempts in the county were treated at Strong Memorial Hospital, the sample is fairly representative of all suicide attempts made throughout the county.

TABLE 2
*Age-Specific Average Annual Rates for Suicide Attempts by Race and Sex**

Age Group	White		Nonwhite	
	Male	Female	Male	Female
0–14	1	2	10	5
15–24	90	238	153	803
25–44	49	129	67	436
45–64	21	44	0	87
65 and over	18	13	0	62
Crude rate	29.91	74.34	48.82	266.08

*Rate is the number of attempts per 100,000 based on the 1960 census of Monroe County.

RESULTS

Of the 1,345 suicide attempts recorded at Strong Memorial Hospital during the study period, 335 (25 percent) were made in 1964, 347 (26 percent) in 1965, 313 (23 percent) in 1966, and 350 (26 percent) in 1967; the yearly average number of suicide attempts was 336. The total number of completed suicides in Monroe County for the four-year period (obtained from county health statistics) was 244, an average of 61 per year. The ratio of suicide attempts treated in our emergency department to completed suicides for the four-year period was 5.5:1. These figures represent an annual rate for suicide attempts treated at Strong Memorial Hospital's emergency department of 57.30 per 100,000 and a county suicide rate of 10.4 per 100,000 for each year of the study period.

Table 1 presents the total group of suicide attempters by age, race, and sex. Eighty-eight percent (1,186) of the total sample were white and 12 percent (159) were nonwhite. Women accounted for 74 percent (1,000) of the total. Eighty-four percent (1,128) fell within the group aged

TABLE 1

Total		323		863		22		137		1,345	

15 to 44. In the white group, 73 percent (863) were women and 27 percent (323) were men, a ratio of approximately 3:1. However, in the nonwhite group, 86 percent (137) were women and only 14 percent (22) were men, a ratio of 6:1, which is quite different from that of the white group. Age also differentiated the white from the nonwhite group. While 82 percent (978) of the whites were between 15 and 44 years old, 94 percent (150) of the nonwhites were in that age range. There was no nonwhite man older than 45 in the study group.

Table 2 presents the age-specific average annual rates for suicide attempts by race and sex. The combined rate for whites was 52.91 and that for nonwhites was 159.57; the overall crude rate was 57.30. In every age group where nonwhite suicide attempts were recorded, the rates were higher for the nonwhites than for the whites. This is especially obvious for the nonwhite women in the groups aged 15 to 44. Even when the overall rates were adjusted for age, the differences remained; the age-adjusted rate for nonwhite women (268.12) was nearly four times that of white women (74.19), and similarly the rate for nonwhite men (44.87) was approximately 1.5 times the rate for white men (29.68). In some cases, the reported rates are based on relatively small frequencies, since only a few suicide attempts were recorded in some age groups and the total number of nonwhite suicide attempts was relatively small in terms of overall frequency.

Table 3 presents the socioeconomic levels of the suicide attempters in the sample. As can be seen, levels IV and V were overrepresented. These two levels accounted for 33 percent (449) of the attempters but represented only 19 percent of the total county population. Although socioeconomic levels I and II accounted for 38 percent of the total county population, only 28 percent (382) of the sample was from these two levels. In the white group, persons from socioeconomic levels IV and V represented 27 percent (315) of the attempts, while in the nonwhite group 84 percent (134) were from these two levels. In contrast, socioeconomic levels I and II accounted for 32 percent (377) of the white attempters but only three percent (five) of the nonwhites.

The relationship of marital status, race, and sex of the suicide attempters is presented in table 4. Examination of the marital status in terms of race and sex revealed that only 38 percent (61) of the nonwhite suicide attempters were married compared with 50 percent (594) of the white group. Among nonwhite men, 55 percent (12) of the suicide attempters were single and among the nonwhite women 28 percent (39) were separated. These two rates are in marked contrast to those for the white group and appear to account in large part for the different rates of married people in the white and nonwhite groups.

The relationship of psychiatric diagnosis given at the time of the suicide attempt to race and sex is presented in

TABLE 4
Suicide Attempts by Marital Status, Race, and Sex

Total	323		863		22		137		1,345	

table 5. Individuals who had a diagnosis of psychotic disorder (schizophrenia, affective psychosis, or organic brain syndrome) represented 16 percent (212) of the total group. The diagnoses of neurotic disorders or character disorders made up 64 percent (867) of the total sample. Most of the 11 percent (154) classified as "other" received a diagnosis of adjustment reaction. For the remaining eight percent (112), there was no psychiatric diagnosis other than the recorded suicide attempt. Examination of the relationship of diagnosis to race revealed that for the total group of suicide attempters the diagnosis of psychotic disorder was made more frequently for the white group than for the nonwhite. For the white group, 25 percent (79) of the men and 13 percent (117) of the women were diagnosed as psychotic, while for the nonwhites ten percent (two) of the men and ten percent (14) of the women received a diagnosis of psychotic disorder. The other psychiatric diagnoses given to the nonwhite and white women were similar; however, nonwhite men received proportionately more diagnoses of neurosis or were more often classified as "other" than white men.

Table 6 presents the relationship of psychiatric care received by the suicide attempters to race and sex. Looking at this factor in terms of race, among 30 percent (353) of whites the suicide attempt represented the sole psychiatric contact, while this was so for 52 percent (82) of the nonwhites. And although 62 percent (738) of the white patients received care at some time after their attempt, only 43 percent (69) of the nonwhites received care subsequently. The differences in total psychiatric care were also striking when the white and nonwhite groups were examined by sex. For the men in our sample, 78 percent (252) of the white group, compared with 50 percent (11) of the nonwhites, had received some psychiatric care either before or after the attempt was made; all of the nonwhite men and all but 22 of the white men received care after the attempt. Among women, 67 percent (581) of the whites and 49 percent (66) of the nonwhites had received some psychiatric care either before or after the suicide attempt; for all but eight percent (73) of the whites and six percent (eight) of the nonwhites, care was received after the attempt.

As shown in table 7, three percent (35) of those who attempted suicide from 1964 through 1967 had died by the end of 1968; 51 percent (18) were women. All of the deaths in the nonwhite group were among those aged 25 to 44. In the white group, 52 percent (16) were men and 48 percent (15) were women. Ten of the deaths were attributed to suicide. In fact, suicide was the largest single cause of death in the sample and yielded a crude rate for those who attempted suicide of 595 per 100,000 per year. This is 57 times higher than the rate of 10.4 per 100,000

TABLE 6
Suicide Attempts by Psychiatric Care Received, Race, and Sex

per year for suicides in the general population. Of the suicides, three were men and seven were women; eight occurred in persons aged 25 to 44 (two of the men and six of the women). Examination of the suicides by race revealed that no nonwhite deaths were attributed to suicide.

DISCUSSION

Many of the results of our investigation support the findings of previous research. The overall ratio of women to men (3:1), the age distribution, and the marital status of our sample of suicide attempters are all in general agreement with the findings of other studies that have been conducted on this subject (10).

In our sample, we found a suicide attempt rate of 57.30 per 100,000 per year and a ratio of attempted to completed suicides of 5.5:1. If we take into account estimates of the suicide attempts that were treated at other hospitals in Monroe County, we obtain a suicide attempt rate of 74.69 per 100,000 per year and a ratio of attempted to completed suicides of 7.2:1. Even these must be regarded as underestimates, for, as Mintz (5) and others have suggested, many suicide attempts are probably never reported or treated in hospitals.

The overrepresentation of the lower socioeconomic levels in our sample, among both whites and nonwhites, lends support to the finding that the emergency services of general hospitals tend to be used more by the lower classes (11). This overrepresentation suggests: 1) that the suicide attempt rate is higher for people in the lower socioeconomic levels, 2) that they are treated for a wider range of self-destructive behavior than people in other classes, or 3) that people from the upper and middle socioeconomic levels may be treated for suicide attempts in places other than emergency departments of general hospitals, e.g., a private physician's office.

Ninety-two percent of our sample received a psychiatric diagnosis at the time of the suicide attempt; however, relatively few were diagnosed as having a psychotic disorder. For many, the suicide attempt appeared to be only one aspect of more general psychopathology, for some it appeared to have contributed to their receiving psychiatric treatment in the future, and for others it appeared to be the result of a single stressful or disorganized period.

Our study also points out major differences between whites and nonwhites who attempt suicide. Although Hendin (12) has suggested that the rate of completed suicide is higher for younger nonwhites than it is for whites and some suggestions have been made in the literature concerning the higher suicide attempt rates for nonwhites, relatively little has been done in the past to systematically examine racial differences. The data from this investigation suggest that white and nonwhite groups who attempt suicide are two distinct populations that may require different predictive, intervention, and treatment methods. The rate of attempts by nonwhites was 160 per 100,000 per year, compared with 53 per 100,000 per year for whites. The ratio of women to men for nonwhites was 6:1, in contrast to the ratio of 3:1 for whites. The nonwhite group was also younger and more often came from the lower socioeconomic levels. Marital status also separated the whites from the nonwhites. Although the majority of attempts in both groups were made by married or single persons, nearly a third of the nonwhite women were either separated, divorced, or widowed and more than half of the nonwhite men were single. In addition, fewer nonwhites had received psychiatric care either before or after the suicide attempt and nonwhites were less often diagnosed as having a psychotic disorder than whites.

These results could be interpreted as reflecting a lesser degree of psychological disturbance in the nonwhite population, as well as a difference in motives and dynamics between the whites and nonwhites who attempt suicide. However, the data could also be interpreted as reflecting different patterns of care or access to treatment for the nonwhite and the white groups. The lower proportion of nonwhites who received care before and after the attempt could be the result of the availability of fewer facilities to nonwhites or of the reluctance of nonwhites to use existing psychological services or to follow through with referrals. The data could also reflect different diagnostic biases on the part of mental health professionals, or even a "screening-out" process that may selectively exclude nonwhites from treatment. Further research is needed to determine which factors or combinations of factors are involved in these observed differences in diagnosis and patterns of care between the white and nonwhite groups.

There was also a noticeable difference between white and nonwhite groups in the incidence of completed suicide. The high risk for suicide in the suicide attempt group is most impressive among whites. Also of interest is the relatively young age at which the suicides occurred and the relatively short time span between the suicide attempt and the successful suicide. Although nonwhites accounted for 11 percent of the total number of deaths, none was due to suicide, while 32 percent of the white deaths were. This result is somewhat surprising since, for the total county population, nonwhites have a suicide rate of 8.98 per 100,000 per year while the rate for whites is 10.51 per 100,000 per year. Since nonwhites who commit suicide do not as often have a history of attempts, the attempts may not be as predictive of future suicides as they are for whites. For whites, the suicide rate among those

who had previously attempted suicide was much higher than that for whites in the general population. The rates for completed suicide among white suicide attempters were 743 per 100,000 per year for white men and 649 per 100,000 per year for white women, yielding an overall crude rate of 675 per 100,000 per year. This contrasts with an overall rate of 10.51 per 100,000 per year for suicides by the white population of the county as a whole. These findings suggest that among whites the likelihood that a person will commit suicide after an attempt is nearly 64 times as great as for someone in the general population. For nonwhites, however, suicide attempts appear to be negatively related to further self-destructive behavior. These results tend to support the conclusion that the nature of the suicide attempts of whites and nonwhites form two distinct patterns and should not be looked upon or investigated as a common problem with similar motives or prognoses.

This study indicates that people who attempt suicide can be differentiated by race in terms of demographic characteristics, diagnosis, psychiatric history, and the incidence of subsequent successful suicide. It further points out that even though relatively few nonwhites may be treated for suicide attempts compared with whites, the rates of suicide attempts in the nonwhite population are much higher. When treating people for suicide attempts, the physician may note differences between whites and nonwhites in the motivation for the attempt, the treatment techniques that are required, and the degree of risk for further psychiatric difficulty and/or suicide. It is vital that professionals working in the emergency services of general hospitals who deal with people from the lower socioeconomic classes, as well as with proportionately greater numbers of nonwhites than whites, be aware of these differences. In future research on suicide attempts, it would seem imperative to consider race as a separate factor. Not only are there clear differences between the groups but, when the groups are considered together, little information about the nonwhites is uncovered, since there is a relatively large ratio of white to nonwhite suicide attempters in most communities.

A Survey of Physicians' Attitudes and Practices Regarding Erotic and Nonerotic Contact with Patients

BY SHELDON H. KARDENER, M.D., MARIELLE FULLER, AND IVAN N. MENSH, PH.D.

An anonymous questionnaire survey of a random sample of 460 physicians revealed that most psychiatrists, obstetrician-gynecologists, surgeons, internists, and general practitioners did not believe in the efficacy of or engage in nonerotic physical contact with their patients. Five to 13 percent of the respondents indicated that they engaged in erotic behavior with patients and five to 7.2 percent engaged in sexual intercourse specifically. The authors point out the need for greater openness and acceptance of discussion about and research in this highly sensitive and vital area.

THE HIPPOCRATIC OATH'S inclusion of an injunction against seducing one's patients clearly delineates this as an age-old concern of physicians. In practicing the art of medicine, doctors have been ethically obliged to judiciously distinguish between transmitting care, comfort, and reassurance in the "laying on of hands" or else transgressing into nontherapeutic or antitherapeutic practices. A combination of factors, including long-standing cultural taboos regarding the discussion of sexual matters, a need to maintain the idealized image of the physician growing out of a priest-practitioner heritage, and rampant ignorance due to a lack of adequate research, have contributed to the maintenance of mythology in all matters sexual. Where there is no fact, fantasy and fallacy flourish.

The historic (1) initial efforts by Ellis, Krafft-Ebing, Freud, Van de Velde, Kinsey, and, currently, Masters and Johnson have attempted to dispel ignorance by providing knowledge that prepares the physician to be of help to his patient. But is the physician, who is subject to the same cultural forces of sexual repression as his patient, prepared to be of help? In order to meet this challenge an increasing number of medical schools in the United States have instituted courses of instruction in the management of sexual disorders (2, 3). With this heightened focus of attention, there logically follows a recrudescence of old concerns regarding the role of the physician himself in relation to his patient.

Reactions to therapists who advocate sexual intimacy as therapeutic (4, 5) have been swift, strenuous, and condemnatory. Others (6–10) have written urging that while such responses may be appropriate, they should be the outgrowth not of blind reaction but rather of serious considerations and open-minded contemplations of the ethical, moral, and therapeutic issues involved, which allow for honest exploration of the question of sexual relations between physician and patient. They point out that guidelines for conduct are blurred and uncertain, as demonstrated by the introduction of each new therapeutic maneuver, i.e., nude marathons, "feeling" therapy, encounter groups, and emergence of a new morality. Further, these authors acknowledge the absence of and need for open discussion, critical appraisal, accumulation of a data base, and honest attempts to develop measures of therapeutic effectiveness.

It is within this spirit of scientific inquisitiveness, which acknowledges both the emotional sensitivity of the subject matter and the absence of existing data, that a pilot study was initiated to determine attitudes and practices of physicians regarding the use of nonerotic and erotic contact with patients.

METHOD

A 32-item, one-page questionnaire was designed that inquired about the respondents' age, years in practice, marital status, and the extent to which they attempted to treat sexual problems in their practice. Six questions followed that asked about their beliefs and practices regarding nonerotic contact with patients. Similarly, seven questions inquired about erotic contact with patients. Respondents were then asked to specify the actual number of patients involved in erotic contact excluding and including sexual intercourse. A final space allowed for other comments. Erotic behavior was specifically defined as that behavior which is primarily intended to arouse or satisfy sexual desire. Most of the questions, except for subjective and demographic ones, were to be answered by circling "0" (never), "1" (rarely—defined as less than five percent of professional experience or opinion), "2" (occasionally—less than 25 percent), "3" (frequently—more than 50 percent), or "4" (always). Two questions required replies specifying the actual number of patients with whom the respondent had had erotic contact.

The authors are with the Department of Psychiatry, School of Medicine, University of California at Los Angeles, Center for the Health Sciences, Los Angeles, Calif. 90024, where Dr. Kardener is Adjunct Associate Professor, Ms. Fuller is Research Associate, and Dr. Mensh is Professor of Medical Psychology.

Computer assistance for this work was obtained from the Health Sciences Computing Facility at UCLA, which is funded by Public Health Service grant RR-3 from the Division of Research Resources, National Institutes of Health.

TABLE 1
Responses to the Question "Do You Attempt to Treat Sexual Problems in Your Medical Practice?" by Percentage

GP	101	7	34	42	18

A total of 1,000 male physicians were selected by random sampling from the membership list of the local county medical society (N=approximately 10,000). The study sample represented the five specialty groups of psychiatry (P), obstetrics-gynecology (OBG), surgery (S), internal medicine (IM), and general practice (GP), with 200 physicians in each group. The questionnaires identified only the respondents' specialty and were otherwise totally anonymous. Each was mailed with an explanatory cover letter and a stamped, addressed return envelope. The physicians' responses were tallied and the data studied by contingency table analysis (Biomedical Program BMD02S). Chi-square tests were used to determine significant differences between the groups thus analyzed.

RESULTS

General Data

Forty-six percent of the physicians responded (N=460). Four questionnaires were defaced with derogatory or profane comments. There were three letters of complaint that objected to the study and alluded to a (never specified) number of additional physicians who were offended. The questionnaire was sent only to male physicians and did not distinguish between homosexual and heterosexual relationships, since the study concerned itself with attitudes toward eroticism generally. In order to preserve anonymity, the only identifying characteristic known to the investigators was specialty. Therefore this is the only information available regarding nonrespondents.

By specialty, 25 percent of the respondents represented psychiatry (N=114); 23 percent, general practice (N=105); 19 percent, internal medicine (N=89); 18 percent, obstetrics-gynecology (N=83); and 15 percent, surgery (N=69). Chi-square tests indicated a significant difference among the five specialties' response rate ($p<.01$). Forty-two percent of the total respondents were 40 to 49 years old (N=194), and 33 percent were 50 to 59 years of age (N=151). Twenty-six percent reported being in practice for 11 to 15 years (N=117), 31 percent for 16 to 24 years (N=144), and 20 percent for 25 years or more (N=93). Eighty-six percent were married (N=393), three percent (N=14) single, eight percent (N=34) divorced or separated, and three percent (N=14) widowed. (Five respondents did not answer the question about marital status.)

There was a significant difference ($p<.05$) between the number of respondents who reported no prior marriages (81 percent, N=221) and those with one or more prior marriages (19 percent, N=51). The frequency distribution of those with no prior marriages was as follows: surgeons, 96 percent (N=44), obstetrician-gynecologists, 85 percent (N=39), internists, 81 percent (N=46), psychiatrists, 75 percent (N=46), and general practitioners, 74 percent (N=46).

In response to the question "Do you attempt to treat sexual problems in your medical practice?" the five groups responded in significantly different ways ($p<.01$) (table 1). This was due primarily to the differences between psychiatrists and obstetrician-gynecologists as compared to surgeons.

Nonerotic Behavior

Table 2 presents the data obtained in response to two questions regarding nonerotic behavior. Psychiatrists and obstetrician-gynecologists were significantly different in their beliefs, as compared to their internist and general practitioner colleagues ($p<.01$). Practice paralleled beliefs regarding nonerotic behavior with patients, again distinguishing psychiatrists, obstetrician-gynecologists, and surgeons from internists and general practitioners ($p<.05$). The response to questions regarding who initiates such practice indicated that, if it is the doctor, he will most likely be an internist or general practitioner ($p<.01$). Except for the nine percent (N=38) of the physicians who were frequently or always the initiator, all specialties reported that it was most often the patient who

TABLE 2
Responses to Two Questions Regarding Nonerotic Behavior with Patients, by Percentage

Category	N	Never	Rarely	Occasionally	Frequently or Always
"Do you believe nonerotic hugging, kissing, affectionate touching of patients may be beneficial to their treatment?"

initiated the nonerotic contact, less often was it mutually initiated, and least often by the physician.

In response to the question "Do you believe such behavior would be misunderstood?" significant differences ($p<.05$) existed among the specialties ($N=430$). This was due primarily to the difference between psychiatrists, 69 percent ($N=94$) of whom believed that it would occasionally, frequently, or always be misunderstood, as compared with 40 percent ($N=66$) of the internists. The distribution of responses for the other specialties believing such behavior would occasionally, frequently, or always be misunderstood is as follows: obstetrician-gynecologists, 59 percent ($N=64$), general practitioners, 51 percent ($N=66$), and surgeons, 48 percent ($N=53$).

A subjective-response question asked under what circumstances nonerotic physical contact (holding, hugging, kissing) might be beneficial. Of the physicians responding, 74 percent ($N=184$) recognized the value of such behavior, particularly for providing comfort and in giving tangible support to a patient. The major specialty group explaining the value of this behavior were psychiatrists, 71 percent of whom ($N=53$) in previous responses (table 2) were shown to be least likely to believe in or to engage in nonerotic behavior with their patients.

Erotic Behavior

The data in table 3 indicate responses to several questions regarding erotic behavior with patients.

Erotic behavior other than intercourse tended to consist primarily of kissing; less often of manual or oral stimulation of the patient's genitals; rarely, such stimulation of the physician's genitals; and least of all, mutual genital stimulation.

To the open-ended question "Under what circumstances might erotic behavior be utilized in treatment?" 87 percent ($N=193$) of the respondents reported that it is never of benefit. Their statements included comments on ethical proscriptions, destructiveness to the doctor-patient relationship, dangerous loss of physicians' objectivity, injunctions in the Hippocratic oath, and comments that such behavior was "censurable," "unforgivable," and constituted "professional suicide" or was prima facie evidence of severe psychopathology in the physician. Explanations for the usefulness of erotic practices were offered by 13 percent ($N=28$) of the respondents and included such statements as "improves sexual maladjustments," "helps patients' recognition of their sexual status," "especially in the depressed, middle-aged female who feels undesirable," "for teaching sexual anatomy," "disclosing areas of sexual blocking," "for specific sexual problems [by being a normal partner]," "to demonstrate there is no physical cause for absence of libido," "to relieve frustration in a widow or divorcée who hasn't yet re-engaged in dating," "in mature patients flowing with nonconflicted [love] feelings," and "in healthy patients by mutual consent making the therapy go faster, deeper, and increases dreams."

There was significance ($p<.05$) between these two groups of responses. This was due to the proportionately larger number of surgeons ($N=6$) who favored the use of erotic behavior with patients as contrasted with general practitioners ($N=1$) so stating. In addition, ten psychiatrists, six obstetrician-gynecologists, and five internists gave responses favoring erotic behavior with patients.

TABLE 3

Responses to Three Questions Regarding Erotic Behavior with Patients, by Percentage

Category	N	Never	Rarely	Occasionally	Frequently or Always
"Do you believe erotic contact with a patient may be beneficial?"					
Total	450	80	15	3	1
P	112	80	17	3	0

IM	71	99	0	0	1
GP	83	93	5	1	1

A separate question asked for the actual number of patients involved with the physician in erotic behavior, specifically *excluding* intercourse. Of the responses, 89 percent ($N=277$) reported no such patient contact, while 11 percent ($N=33$) indicated affirmatively by specifying the number of patients so involved. Of those who responded affirmatively, 70 percent ($N=23$) reported that it occurred with fewer than five patients. Similar inquiry was made regarding the actual number of patients involved with the physician in erotic behavior, specifically *including* intercourse. Of these respondents, 89 percent ($N=263$) reported no such contact, while 11 percent ($N=33$) acknowledged such experiences. Of those who reported intercourse with patients, 79 percent ($N=26$) indicated that it involved fewer than five patients.

The four questions "Do you engage in erotic practices?" (table 3), "Would this include intercourse?" (table 3), "How many patients involved, excluding intercourse?" (table 4), and "How many patients including intercourse?" (table 4) served to delineate the incidence of erotic practices. A total of 59 physicians answered one or more of these four questions, while 33 respondents provided information for the last two questions. These data are presented in table 4. The distribution of responses was not statistically significant.

The results of these four questions would indicate that five to 13 percent of the total sample ($N=460$) engaged in

GP	105	14	13	3.0	9	9	2.0	9	9	2.0

some kind of erotic behavior with their patients (tables 3 and 4). Similarly, the incidence of erotic behavior, specifically including sexual intercourse, was five to 7.2 percent (tables 3 and 4).

A final space on the questionnaire provided for additional comments; it elicited 124 responses, which were sorted into eight categories. General comments, one of the eight categories, comprised 47 percent (N=58) of these responses and included discussions of the problems that would result from erotic behavior, questions about methodology, and an urging for more teaching in medical schools of sexual matters and for special seminars on this subject for practitioners. Four respondents (three percent) acknowledged that they knew "such things [erotic behavior] go on." Nine (seven percent) stated that sexual behavior should be kept out of the office. Twelve (ten percent) stated that erotic behavior was symptomatic of a doctor's illness. Nine (seven percent) indicated that they did not know if erotic behavior was beneficial or not. Fifteen (12 percent) felt that such behavior destroyed the doctor-patient relationship. Five (four percent) indicated great anger that this study was undertaken, i.e., "proves psychiatrists are nuts," "an insult to even be asked," "you're sick." In contrast, 12 of the respondents' comments (ten percent) were of a congratulatory nature applauding the effort and encouraging continued study.

DISCUSSION

The questionnaire afforded respondents a unique and anonymous opportunity for the expression of participation in unusual practices, and the data are therefore more likely to be representative of such practices. Each specialty represented tended to have its own slightly different orientation regarding engaging in the treatment of sexual problems and beliefs and practices regarding both erotic and nonerotic behavior with patients.

Psychiatrists and obstetrician-gynecologists reported a much higher frequency of the treatment of sexual disorders in their practices and were also more wary of nonerotic physical contact than their colleagues, since they primarily believed that such behavior would be misunderstood. At the same time, it was the psychiatrist who most often explained why such contact might be beneficial in the treatment of a patient. Internists and general practitioners, on the other hand, indicated a belief in and practice of beneficial, nonerotic physical contact with their patients. While surgeons differed sharply from the other respondents in overall response rate and frequency of treating sexual problems, they were, nonetheless, more allied with psychiatrists and obstetrician-gynecologists regarding beliefs and practices of nonerotic physical contact.

The questions regarding actually engaging in any erotic behavior with patients, and in sexual intercourse specifically, indicated a lower incidence (five percent) than did those questions asking for a specific number of patients involved in any erotic behavior (13 percent) and in sexual intercourse specifically (7.2 percent). Possible explanations for this variance include: 1) these questions differed from the others by requiring that a specific number be given and 2) they appeared later in the questionnaire, apart from the patient management considerations per se. Further, physicians participating in this kind of activity with patients do so because they feel they have both a professional and a separate social relationship with these patients. Several respondents specifically gave this explanation on their questionnaires.

It was in the area of belief—not practice—that erotic contact may be beneficial that the surgeons differed from the other respondents (table 3). They constituted 26 percent (N=17) of the total sample of 19 percent (N=88) of physicians who believed that such behavior might be beneficial. Twenty percent of the psychiatrists (N=22) held this view.

It may be worthwhile to compare these responses (19 percent) by physicians with those of medical students, since the latter group represents an earlier phase in the professional career. Wagner (11) reported that 25 percent of the freshmen medical students surveyed felt that sexual intercourse with a patient could be appropriate under the "right circumstances" if the doctor was "genuine" and "authentic." These figures delineate a core of both physicians-in-training and physicians-in-practice, separated by years of age and years of medical practice experience, who are seriously asking, "Why not?" It is a question deserving of an answer and represents an important

challenge to medical teachers engaged in sex education. A greater understanding of the emotional parallel between the doctor-patient and parent-child relationships may provide such an answer. Of particular interest in this regard is Woodbury and Schwartz's study of parent-child incest (12), which indicated an incidence similar to that of the doctor-patient erotic contact reported here.

Answers to Questions of the Month

Page 1070. Question 1:C; Question 2:E.

Psychiatry in Shanghai, China: Observations in 1973

BY DAVID N. RATNAVALE, M.D.

At the invitation of the Chinese Ministry of Health, the author visited China earlier this year. He describes the structure and organization of the Shanghai Psychiatric Institute, a therapeutic community in which the staff and patients work together in a classless social organization, which is part of a medical system that blends the modern and the ancient traditional medical practices. The author presents brief general information on acupuncture and describes its use in psychiatry, but stresses the preeminence of group activities in the therapy of mental illness.

THE CLINICAL MANAGEMENT and care provided to persons suffering from psychiatric illness cannot be described in isolation from the cultural, social, economic, and political milieu from which they spring. Hence, the interpretation of modern trends in a land as ancient and as immense as China is no ordinary task. The problem is further compounded by our scientific requirement of perceiving change through Chinese senses while maintaining an objective investigatory posture.

The people of China, when faced with psychological issues, are reputed to have ready mental access to a vast compendium of "old Chinese sayings." This may simply give them time to ponder before reacting, but it reveals plainly their reverence for the ancient and their readiness to connect the past and the present.

We are now seeing the consequence of Chairman Mao Tse-tung's call during the Great Leap Forward in 1958: "Chinese medicine and pharmacology are a great treasure house. Efforts should be made to explore them and raise them to a higher standard." He has given impetus to the study of ancient Chinese medicine and modern medical science contemporaneously; through the vigorous pursuit of this national policy he has substantially reoriented the entire system of medical practice and teaching in China. Psychiatrists and mental health workers in China tell us that the developments in their psychiatric services parallel the growth observable in all other spheres of human activity and thought since the "liberation" of 1949.

I was invited by the Ministry of Health and the staff of the Shanghai Psychiatric Institute to study current psychiatric practice in China and to share my research experience in Sri Lanka (formerly Ceylon), where I had investigated the difficulties inherent in any attempt to blend the ancient indigenous (ayurvedic) medical system with Western medicine. This paper presents a description of a hospital in Shanghai, one of the world's largest cities, in the Kiangsu Province of the People's Republic of China. I shall attempt to identify modern trends in psychiatry and the therapeutic modalities in use. Special attention will be paid to acupuncture in psychiatry and therapeutic group processes.

At the time this paper was written, Dr. Ratnavale was a senior psychotherapist at Chestnut Lodge, Rockville, Md. He is now Associate Professor of Psychiatry, Eastern Virginia Medical School, 721 Fairfax Ave., Norfolk, Va. 23507.

SHANGHAI PSYCHIATRIC INSTITUTE

The Shanghai Psychiatric Institute, constructed in 1958, is a large complex of modern concrete buildings situated in a surburban section of Shanghai. The 1,000-bed hospital and the specialized departments that serve it cover half the total area of the premises (40,000 square meters), which itself is enclosed by a cinnamon-colored wall three meters high. Directly across the road—Chin Chi Road—lies the impressive Lon Hwa General and Teaching Hospital.

As one enters the imposing gates of the Shanghai Psychiatric Institute, one's gaze is met by a tall rectangular slab of cement bearing a quotation of Chairman Mao Tse-tung about freedom. The buildings of the institute surround a spacious garden-like courtyard where patients are seen at play; it is tastefully landscaped with flowering and evergreen trees.

The hospital is divided into 13 airy and plainly furnished units with rooms that sleep eight to 16 patients. The patients have the responsibility for maintaining their quarters but are assisted in this function by the nurses and health workers. There are a few single rooms but these are rarely used, since the isolation of patients is strongly discouraged. On one wall of every unit is painted an appropriate quotation from Chairman Mao, e.g., "Help one another; care for one other; love one another."

The Psychiatric Institute is served by a staff of 556 persons. Fifteen administrators, four of whom are psychiatrists, under the chairman of the revolutionary committee of the hospital, are responsible for managing the institution. Dr. Yen Ho-Chun, a psychiatrist, is the medical director. His assistant, Dr. Shu Sun-Ha, is also the vice-chairman and has just completed two years of specialized instruction at a famous center for Chinese traditional medicine. Of the 61 psychiatrists, 11 are women. All have received training in both modern Western medicine and traditional Chinese medicine.

At any given time as many as a third of the staff psychiatrists are away in rural areas serving with other specialists on mobile medical teams for as long as six to 12 months. There they are engaged in treating patients, instructing commune and barefoot doctors (*chú chiao*—"a peasant who has had basic medical training and gives treatment without leaving productive work" [1]), and disseminating information on mental health. Their rural encounter is also considered to be a learning experience.

A distinctive feature of the working staff of the hospital, which includes 218 nurses, is the absence of any insignia of rank. Indeed, my overall impression was that staff members were under less stress than their fellows in other lands and I was struck by the ease of conversation among professional, paraprofessional, and patient.

The Shanghai Psychiatric Institute and similar institutions provide treatment facilities for the whole society; it is asserted that, in the preliberation period when adequate health care was available only to the privileged classes, "hospitals did not satisfy the needs of the people." The patients are now receiving the benefits of both the traditional Chinese and the modern Western medical systems and treatment is provided for all types of mental illness. The outpatient clinic is reported to receive as many as 400 patients a day, the majority suffering from neurotic and psychosomatic conditions. A small percentage of patients with epilepsy are also seen for checkups or renewal of medication. On the average, hospitalization lasts for ten to 12 weeks and families generally visit patients twice a week. There is no charge for therapy, but a small payment is sometimes levied for food.

There is no separate staff category that corresponds to our social workers. The functions of social work are absorbed by the working staff, who maintain steady contact with families and with members of the patients' working units. Every patient is certain that his job will be waiting for him when he returns to work.

The inpatients range in age from 20 to 35. The incidence of psychiatric disorders below the age of 15 is said to be very low. Indeed, the absence of aged, regressed, or agitated patients is also striking. Over half the patient population suffers illness of psychotic proportions, chiefly schizophrenic syndromes. The psychiatrists are unanimous in their claim that the incidence of depressive syndromes (*yu yiu-tsen*), postpartum psychosis, and suicide is significantly low. They also note the rarity of senile psychoses—an observation recorded by Tsung-Yi Lin in another Chinese community (2).

They also asserted that chronic alcoholism, opiate addiction, and drug abuse in general had been eliminated, and I concur with the group of American physicians who visited China in 1971 that "not a single instance of drunkenness was observed day or night in our travels in the cities and countryside" (3). Our Chinese colleagues attribute their success partly to widespread educational campaigns and partly to the efficient halting of illicit production. Lowinger (4) considered "the changed ideology of the young people . . . the changes in outlook, which included a redefinition of the nation and its youth, of their worth and role" to be a major force. Indeed, the eradication of the poppy fields in a land that is 80 percent "countryside" and the recultivation of these fields with food crops indicates the size of the task and the efficiency of the programs.

The newer developments within the Shanghai Psychiatric Institute are identified with parallel changes in the nation as a whole; they indicate that a shift in the attitude toward mental patients and their care followed in the wake of the "great proletarian revolution" under Chairman Mao's leadership. He is quoted frequently as a source of guidance and inspiration and his sayings are conspicuously displayed in all public places. He is seen as a true advocate of the classless society, in which all hospital workers and all patients belong to one socioeconomic category, and all remember his exhortation to approach patients "with wholeheartedness," "paying attention to environment and past beliefs." He sponsored the revival of ancient and traditional medicine (including acupuncture) and the establishment of equal status for modern Western-oriented physicians (*si-i*), barefoot doctors (*chú-chiao*), and traditional healers (*zjung-i*).

The physicians and health workers at the Psychiatric Institute emphasized the point that, in line with the concept of a people's republic, the hospital is perceived as a people's hospital, and they were generally inclined to view each ward or hospital unit as a family.

TREATMENT: METHODS AND PHILOSOPHY

The preeminent therapeutic emphasis appears to be related to the reestablishment of a "sense of group" or "sense of belonging." The group therapeutic activities include ideological education, play, singing, reading, and "heart-to-heart talks." One can add "group acupuncture" to this list since acupuncture is now administered to more than one patient simultaneously. Chemotherapy, herbal medicine, and acupuncture comprise the nonpsychological approaches. Electroconvulsive therapy and insulin shock treatment have been discontinued.

Chemotherapy

The standard Western psychopharmacological products (e.g., tricyclic antidepressants and phenothiazines) are used, along with herbal preparations. In general, the dosages are smaller than those prescribed in the West; 250 mg. of chlorpromazine per day is considered to be a high dose. It is suggested that the concurrent administration of herbal medicines reduces the need for higher dosages. The Psychiatric Institute maintains a large herb pharmacy that dispenses pills and decoctions manufactured from medicinal roots, bark, and leaves.

Acupuncture

Acupuncture appeared in Central Asia as early as the Neolithic period and its application has been passed down to us through a few records. An extensive exposition is found in the *Huang-ti Nei Ching Su Wen* [*The*

Yellow Emperor's Classic of Internal Medicine] (5), whose composition is placed by some authorities at 2697 B.C. and by others at the third to fifth century B.C. (6). A textbook, it takes the form of a dialogue or "familiar conversations" between Huang-ti the Emperor and his minister-physician Ch'i Po. Students of Chinese medicine look to the *Nei Ching* not only to read medical history, but also to understand its development and current usage.

Acupuncture consists of the insertion of needles into particular points on the body that lie along 12 channels or *ching* (*ching lo* theory). These *ching* are said to be deeply set and not in direct communication with the blood vessels but to emerge to the surface at 365 or more places, presenting the points for needling. The anatomical locations of these *ching* have yet to be defined. Acupuncture, which is widely practiced in China, involves an understanding of the principles of *yin* and *yang*, maintaining a balance between *ch'i* (air) and *shiueh* (blood), and "needling," which establishes equilibrium by removing stagnation and neutralizing excesses.

The use of acupuncture in psychiatry and anesthesia is of relatively recent origin. Though its use in psychiatry has not been adequately reported in the literature, despite its regular use in Chinese mental hospitals, acupuncture anesthesia has won considerable publicity and is extensively employed in China (by conservative estimate it has been used in more than 400,000 operations since 1968) with a 90 percent reported success rate.

The Melzack-Wall hypothesis (7) offered some hope of a neurophysiological explanation for acupuncture anesthesia, but the answer remains unsettled. This hypothesis holds that perception of pain involves a "gate control" system, primarily located in the substantia gelatinosa of the spinal cord, and that effective closure of this "gate" blocks pain from reaching the higher centers. Man and Chen (8) postulated that there is a second gate in the thalamus, while others have summarily dismissed the phenomenon as something that makes "no sense anatomically" or that it is due simply to the effect of distraction and hysteria. Even serious students have been vocal about the "power of suggestion," but they are hard pressed to explain what they mean. Cooperative exploration by psychologists, psychiatrists, and neurophysiologists is surely called for. Huard and Wong (6), reporting on acupuncture in psychiatry, noted that "in psychiatry the effect of acupuncture is nonexistent, and hysterical and coxalgic patients have been seen to resist the needles but not the electric shock" (p. 215). Sidel (9) has reported the use of acupuncture in treating schizophrenia, excitement, catatonia, and depression.

I observed the administration of acupuncture to patients individually and in groups at the Shanghai Psychiatric Institute, where acupuncture has been in use since 1966 and is now standard treatment. Psychotic and neurotic patients are given acupuncture along with other types of treatment. It is considered particularly helpful in treating syndromes characterized by excitement, anxiety, apathy, catatonic stupor, and depression. Points on the limbs and trunk have been identified for needling in psychiatric conditions; they lie along the standard *ching*, but why these points have been selected over others has still to be explained. Future research must satisfy this question and also establish the specific value of this form of treatment.

Eleven points reported to be specific for psychiatric illness are: *ho ku*, a *yang ching* on the extensor aspect of the hand in the muscle belly of the first dorsal interosseous muscle; *nei kuan*, a point on the flexor aspect of the forearm one inch from the wrist crease; *lau kong*, in the center of the palm; *shiao shang*, a *ying ching* on the outer aspect of the nail bed of the thumb; *tsu san li*, a point one inch below and behind the head of the fibula; *tai shung*, on a line between the first and second toe, two fingerbreadths above the web; *yung chuwan*, on the sole of the foot at the junction of the anterior and middle third; *yi fong*, on the posterior aspect of the ear lobe; *tin kong*, immediately anterior to the tragus of the ear; *bei wei*, on the center of the scalp; and *tai yang*, at the temple.

During acupuncture the patient usually complains of a mild local "soreness," "distension," or "tightness." Manual twirling of the needle is still practiced but more commonly a current of four to six volts is passed to the implanted needle via a portable regulator box no bigger than a small transistor radio. The box, with several terminals, allows for treating more than one patient (as many as six) at a time and requires only one therapist. Each treatment lasts 20 to 30 minutes and is administered twice daily, daily, or three times a week. A positive response (essentially the reduction of symptoms) is usually noticed after two weeks of treatment, but the course generally lasts from five to six weeks. If no improvement is noted in three weeks the method is discontinued.

The doctors at the Shanghai Psychiatric Institute implied that acupuncture has replaced ECT in their hospitals but they do not, at this stage, venture any definite explanation of its action. They list its advantages over ECT and note primarily its safety, simplicity, and availability and the absence of such side effects as memory impairment. It must be emphasized that doctors and scientists in China make no pretense of fully understanding the action and effect of acupuncture and that active research is going on in this area.

Therapeutic Group Processes

Group play at the Shanghai Psychiatric Institute chiefly involves uncomplicated noncompetitive games. Groups of patients are seen lobbing a basketball to one another in a game that resembles "catch." Another game consists of tossing a rubber ball or shuttlecock to a partner with a wooden paddle. In table tennis, however, a little of the competitive spirit is evidenced.

In group singing patients and nurses stand around a pianist and violin player and sing animated folk songs or songs of victory that have a somewhat martial flavor and that deal with liberation and freedom.

In group reading patients or health workers take turns reading simple literary works, news reports, or children's books.

"Heart-to-heart talks" amount to informal chats in small groups or individually with a psychiatrist or nurse.

Ideological Education

By far the most emphasized therapeutic group activity is ideological education. It is given to all patients at some period of their hospital life. A newly admitted acutely disturbed or confused patient does not participate in this mental exercise until the ward psychiatrist, nurse-instructor, and patient group acknowledge his ability to become involved.

This method is aimed at "mobilizing the patient's initiative" through discussions, questions, and the examination of such famous works as the teachings of Chairman Mao. The subject matter is concerned with objectivity, freedom, openness, equality, and caring for one another and represents the basic material for ideological education. Learning and discussing the teachings of Chairman Mao, it should be noted, is a popular and serious activity in all spheres of life in China; reading, studying, and debating his works is considered to be a highly salutary pursuit. It is understandable that this would be a part of hospital life.

In these sessions, asking questions and repeating them until they are satisfactorily clarified is greatly encouraged. There are thus no "stupid questions," only comrades who cannot adequately explain their answers. For example, a group may be engaged in the study of Mao Tse-tung's writing on "Where do correct ideas come from?" or "Can bad things be turned into good things?" This would be the basic material for exploring the ideas and feelings of the patients. In one such discussion, the nurse-instructor (the group leader) expressed the view that, in interacting with patients, a group leader "must not be critical, but instead willing to explore the conflict that led to the patient's puzzlement or false ideas; that an atmosphere of trust must be created and engendered; that investigations and explorations should be wholehearted and intensive."

Case Report

The following report was related to me by a psychiatrist at the Shanghai Psychiatric Institute[1]:

A woman nearing the age of 50 (the usual retirement age) was informed by her working unit that she was going to be retired. She had a "false thought" that she was being expelled and wondered whether she was to be dismissed because her ability and performance were poorer than those of the other workers. She got the idea that if she worked hard she might be offered the opportunity of working two shifts instead of one. She was, of course, actually ill. In addition, she had insomnia and loss of appetite. At the institute her treatment consisted of chemotherapy, acupuncture, and group activities.

In her group, she was urged to compare the past and the present, the time before liberation and the present time. She was reminded that in the past the old workers, the aged workers, were "kicked out by the capitalists" and that it was very difficult for them to obtain any pension or other support. Her "actual" current situation and the new labor regulations that provide certain guarantees were explained to her. She was helped to recognize that there was glory in the work she had already done and that she could retire with the feeling that her career was one that brought glory to herself and to her country. She was helped to see that her thoughts were distorted and therefore wrong. She enjoyed and benefited greatly from her group experience.

Follow-up of her case was carried out at the outpatient clinic; weeks after her discharge the unit wrote to her and she replied with news of her improved state. In cases of this kind, the "visiting team" would go to the patient's home or working place to check on her progress and to help "consolidate the efficiency" of her improved state. Her treatment was therefore a combination of chemotherapy, acupuncture, and group therapy. Follow-up aided in consolidating her gains and facilitating the development of a new relationship between her and her fellow workers.

We are frequently disappointed when our theoretical conceptualizations fail to explain the action or results of techniques unfamiliar to us. The language is the same but the dialects are different, a situation that creates no less misunderstanding than has existed between so-called organicists and those considered psychodynamically oriented.

How are we to understand the clinical example cited or the statement that "ideological education is offered in a way that helps to integrate and reorganize a patient's thinking"? Is it enough to accept therapeutic efficacy simply in terms of realigning illogical thought through a dialectic process (defined as the art or practice of examining opinions or ideas logically, often by a method of question and answer so as to determine their validity), or can we safely assume that other psychological events are taking place concurrently?

We are faced with the task of translating traditional Western concepts concerned with such things as the mother-child relationship, ego development, psychosexual phases, psychic trauma, and transference to the state of affairs that prevails in China and of opening our minds to new ideas. In such a pursuit it would be wise to guard against too hasty a presumption that our Chinese colleagues organize these concepts along similar lines but within a framework that we do not as yet understand. They are willing to share their clinical experience and for this privilege we are obliged to study *with them* the intricacies of the methods they employ. We are called upon to face simple questions related to causation and curability. In a field that has no universal criteria for cure, we must at least be content to accept as a primary consideration a patient's capacity to return to his work and his home life.

If we begin to scrutinize one of the primary psychological therapies practiced at the Shanghai Psychiatric Institute, with an inclination to view it as a form of group therapy, it would be perfectly valid to ask why it receives their main emphasis, what makes it an effective modality, and how it works.

In the West, and especially in the United States, group therapy as a psychotherapeutic method has almost lost the stamp of science. Its exponents vary from psycho-

[1] When I asked whether this patient's case would fit in the category of depressive illness, I was informed that she had received a diagnosis of "involutional melancholia."

analysts to nudists, and it has come to mean (in the public eye) any type of group activity that ameliorates psychic tensions and that facilitates improved interpersonal relationships. Regrettably, there is little consensus regarding the indications for group therapy, although there is general agreement that people who are deprived of adequate group experiences or who are unduly uncomfortable in groups can benefit from such treatment. We also know that cultural and social factors—one's concept of family life, of independence and autonomy, of intrafamily loves and jealousies—all influence attitudes toward one's self and one's fellows.

Reduced to its simplest meaning, group therapy aims at the evolution of a sense of group or the redevelopment of that sense, once known but abandoned. Within this simple context, it might be profitable to consider the meanings of "group sense" to a person in Chinese society today and its value and significance in group treatments in Chinese mental institutions.

The attitude of Westerners toward China has fluctuated considerably during recent centuries and has significantly influenced Western perceptions of the Chinese character. Anthropologists and social scientists speak of the Chinese need to "save face" and their "inscrutability." Western LaBarre (10), writing in 1946, noted that "the Chinese are not militaristic . . . not imperialistic . . . non-mercantile . . . and not essentially an urban people." Weakland (11), in "Orality in Chinese Conceptions of Male Genital Sexuality," discussed their "oral thinking." Hsein Rin (12) noted the marked emphasis on orality in the Chinese, giving as evidence "the frequent and prolonged breast feeding of babies and the prominent and almost exclusive role of mothers in bringing up children." Tsung-Yi Lin (2) observed that "the threshold of Chinese families in regard to abnormal behavior is rather high." Muensterberger (13), in a study of the character of the southern Chinese, wrote that "those who know report that, although the Chinese woman suffers under many restrictions, she plays a more influential role within her family than does the man."

In general, students of Sinitic studies agree that, however alien the surroundings, the fundamental and centrally organizing factor in Chinese social life is the family. That this appears to be true of modern China is hard to dispute, and a discussion of the persistence of this characteristic in the face of radical alterations in role functions and expectations in the present-day Chinese family group is a worthwhile project.

ASPECTS OF GROUP CONSCIOUSNESS

The meaning of the group may well be somehow different in China, but there is evidence to suggest that the group has a highly therapeutic meaning. Interpreting national policy and its influence upon Chinese society is beyond the scope of this paper, but reference must be made to current developments within the nation that appear to significantly enhance group consciousness throughout life. At least four intimately related areas deserve our close attention: 1) the reverence toward children in modern China, 2) the liberation of women, 3) a heightened awareness of the oppressed minorities, and 4) the popularity of "speaking bitterness." Inherent in these phenomena is a recollection of how things used to be and an affirmation of the positive changes that have been made.

Reverence for Children

Despite historical references to poverty-stricken eras when parents were driven to extremes, the Chinese love of children is taken for granted. This basic attitude is being augmented by present-day leadership. Mao Tse-tung has said: "The world is yours, as well as ours, but in the last analysis it is yours. You young people, full of vigor and vitality, are in the bloom of your life, like the sun at eight or nine in the morning. Our hope is placed on you. The world belongs to you. China's future belongs to you."

From very early in an infant's life, as early as 56 days old, he might be placed, like 90 percent of his peers, in the nursing room of the factory where his mother works. She will come to feed him at least twice each day, but during the rest of the working day he is in the care of several "aunties." These aunties, or auxiliary mothers, are selected from among the workers and chosen for their patience, warmth, and heightened sense of responsibility. Thus, quite early a mother begins to rely on other people to assist her in rearing her babies, and the child comes to recognize that he is a member of a group. Indeed, the children feed together, play together, and after breakfast sit on individual potties and have their bowel movements together.

News about new schools and about developments in education is widely disseminated. Under the title "More Nurseries and Kindergartens in Tienstin," the *Chinese Medical Journal* (14) reported: "In addition to singing and dancing lessons, the children learn to tend vegetable gardens and raise chickens and rabbits in order to inculcate in them the love of labor," and under the title "Better Health for Tibetans": "Nurseries and kindergartens are staffed, in the main, by young women who have received special training in child psychology, health protection, and nutrition. Research work is being conducted to improve the care and education of pre-school age children. Meetings of child care workers, for exchanging experiences, are held regularly."

Women's Liberation

It is generally believed that, until recently, women held an inferior position in China and were the voiceless, faceless, footbound servants of their masters, gaining a modicum of status only upon becoming mothers-in-law. New marriage laws, social changes, and raised expectations have altered their traditional postures so that now they kowtow to no one, enjoy equal rights, and receive equal pay for equal work. R. Sidel's observations (15) lend credence to these changes, noting also that basic attitudes toward motherhood remain stable.

Oppressed Groups of Past Days

It is well known that in bygone times peasants and minority nationalities, especially in remote regions, were at the mercy of warlords who plundered their produce and held them in fear and submission. These groups are now enjoying the limelight in a conscious, deliberate manner. The theater, opera, and radio consistently depict their earlier predicament and compare the past with the present. It would appear that the term "minority" is frequently equated with "underprivileged," in a way that expresses the earlier status of the peasant classes (who, though numerically in the majority, were the minority in a social and economic sense).

Speaking Bitterness

"Speaking bitterness" refers to a phenomenon that became very popular and was greatly encouraged after the liberation. Through "speak bitterness" meetings, an acceptable forum was created for people to describe their past hardships in a dramatically cathartic fashion. It served to purge one's impacted resentments and, through identificatory processes, the bitter feelings of their hearers as well. It served also to identify the present politicosocial system as one that rescues and nurtures, but apparently it did not stop there. Rather than foster a helpless dependency, the will of the individual and the group was bolstered into recognizing that only through their group consciousness, vigilance, and hard work could the present gains be protected and sustained.

Only four areas have been portrayed; presumably there are more. They have the quality of novelty and whet one's curiosity. Yet, they sound like old ideas or just ordinary sentiments. They seem to remind us that children have always been cherished—and needed it; that women invariably exerted profound psychological strengths—and needed to; that the oppressed and small at all times found an advocate; and, last but not least, that people have always complained.

I recognize the difficulties inherent in the interpretation of unfamiliar methods and ideas. I would caution against hasty generalizations and urge a deeper study of the topics discussed in this paper.

ACKNOWLEDGMENTS

I wish to thank my Chinese hosts, my colleagues at the Shanghai Psychiatric Clinic, and their patients for their trust and generosity. Without their help and the unhurried assistance of Dr. Yu Lu-yi and both Mr. Chiang and Mrs. Wu Sheu Cheng of Shanghai's Municipal Bureau of Public Health this work would not have been possible.

Evolving Behavior in the Clinical and Experimental Amphetamine (Model) Psychosis

BY EVERETT H. ELLINWOOD, JR., M.D., ABRAHAM SUDILOVSKY, M.D., AND LINDA M. NELSON

A parallel is drawn between several behavioral constellations observed in the evolution of the human amphetamine psychosis and the motor-postural-attitudinal manifestations induced in animals by chronic amphetamine intoxication. On the basis of the results reported, a triple-layered model of psychosis is suggested and the roles played by participating neurotransmitters and mechanisms are further elaborated.

IN A CLINICAL SETTING, the amphetamine psychosis develops over a period of time as the user gradually increases his intake of amphetamine to amounts ranging from 150 to 2000 mg. per day. Although the paranoid psychotic state evolves gradually as a result of this chronic abuse, the patient is seldom seen by a physician until the process is far advanced. By this time he presents a fairly distinct syndrome, with delusions of persecution, ideas of reference, visual and auditory hallucinations, changes in body image, hyperactivity, agitation, and panic.

In previous studies we have asked whether there are behaviors that precede the last stage and may, in fact, be related to the development of the paranoid schizophrenic-like picture. More specifically, we have been interested in the anlagen of the behaviors that evolve over time since several of the antecedent behaviors we have observed in human chronic amphetamine abusers present fairly distinct constellations or clusters (1, 2).

One of these constellations involves an intense feeling of curiosity, often manifested by repetitious, stereotyped examining, searching, and sorting behaviors. This repetitious activity has been variously called "punding" (3), "hung-up activity" (4), "obsessive-compulsive tendencies" (1, 5), and "knick-knacking" (by inhabitants of the Haight-Ashbury scene). Its characteristic feature is engagement in tasks that primarily involve small bits or minutiae and a marked enhancement of perceptual acuity directed toward these minute objects. At times there are perceptuo-motor compulsions, manifested as repetitious stringing of beads or as acts of arranging, sorting, and lining up pebbles, rocks, or other small objects (2). Most of the so-called "speed art" is replete with complicated syntheses of a multitude of minute details, often depicting universal themes or mandalas. Speed users are frequently observed taking apart such objects as television sets, watches, radios, and phonographs. Subsequently, the parts may be analyzed, arranged, sorted, filed, and cataloged and, rarely, put back together (2). Many patients report a sense of satisfaction associated with this compulsive-like conduct.

Perhaps the best-known example of searching and examining behavior is that of Sherlock Holmes, whose cocaine habit was described by Dr. Watson:

> Finally he thrust the sharp point home, pressed down the tiny piston, and sank back into the velvet-lined arm-chair with a long sigh of satisfaction. Three times a day for many months I had witnessed this performance. . . .
>
> "It is cocaine," he [Holmes] said, "a seven-per-cent solution. . . . I suppose that its influence is physically a bad one. I find it, however, so transcendently stimulating and clarifying to the mind that its secondary action is a matter of small moment. . . .
>
> "My mind," he said, "rebels at stagnation. Give me problems, give me work, give me the most abstruse cryptogram, or the most intricate analysis, and I am in my own proper atmosphere. I can dispense then with artificial stimulants. But I abhor the dull routine of existence. I crave for mental exaltation. That is why I have chosen my own particular profession, or rather created it, for I am the only one in the world. . . .
>
> "To the trained eye there is as much difference between the black ash of a Trichinopoly and the white fluff of a bird's-eye as there is between a cabbage and a potato."
>
> "You have an extraordinary genius for minutiae," I [Watson] remarked (6, pp. 610–612).

Holmes's description of his "grooving on" puzzles and cryptograms and his penchant for magnificent synthesis of details to solve a given case are quite analogous to the amphetamine addict's intense curiosity and preoccupation with minutiae. Even at a low point in the drug-use cycle, these persons will seek out stimulating mechanical or intellectual puzzles. This compulsion for analysis is widely recognized in the "speed scene."

Amphetamine addicts frequently state that the early scanning, prying, probing behaviors subsequently evolve into a pleasurable sense of "suspiciousness" in the origi-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

nal meaning of the word—that is, looking beneath the surface for the truth or meaning (literally, "to look from below"). They describe looking for meaningful details or relationships between details.

Another progressive symptom noted by these patients is increased thinking about "meanings and essences." Insights are frequently received as significant major revelations, or "eureka experiences." For example, one patient stated, "I put things together from the past and present. Now I think I know what is going to happen to this world." These sudden emotional insights and the compulsion to analyze a variety of details to find meaning and explanation were common to both philosophical and delusional concerns (2).

Later in the course of amphetamine addiction, the direction of the inquisitive behavior is reversed and the addict feels that other people are probing—watching and spying on him. At this time the previously pleasant suspiciousness takes a more paranoid form, leading eventually to fear or even agitation, hyperreactivity, and panic. The addict may then begin to misinterpret stimuli and often to have illusions and hallucinations. Thus it might be said that the initial periods of pleasurable curiosity and suspiciousness set the stage for the eventual paranoid reaction.

EXPERIMENTAL STUDIES IN ANIMALS

In the experimental laboratory, chronically intoxicated animals manifest evolving clusters of behavior comparable to those just described in amphetamine addicts (7). In our experiments we have used the operational approach that the laboratory observations have heuristic value in elucidating the nature of the amphetamine psychotic state itself; we are summarizing in this paper the animal behaviors that are analogous to those seen in human amphetamine abusers. The details of these experiments, performed on rats, cats, and rhesus monkeys, have been reported elsewhere (7–11).

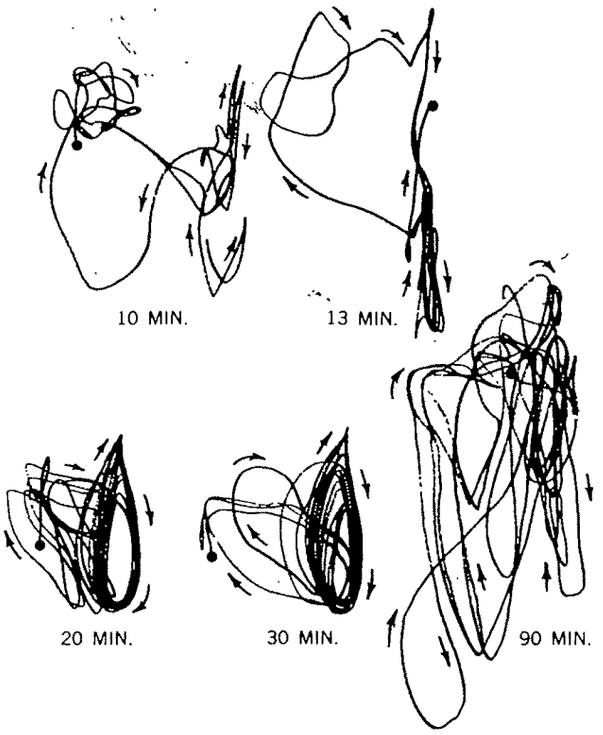
Stereotypies

Stereotyped movements are the hallmark of both acute and chronic amphetamine intoxication. They may consist of a single activity performed continuously or a sequence of a few activities that dominate behavior (8, 12, 13). Usually these stereotypies appear nondistractible and "driven" (performed in a rapid, repetitious manner). They most often evolve from motor components of investigative behavior. In both our acute and chronic intoxication studies across species, the one common denominator of amphetamine-induced stereotyped movements was that they were composed of patterns of searching and examining (10). The motor components, at least, of these patterns are present in the stereotypies of all species studied.

In macrosmatic animals, such as the rat, the primary stereotyped mode is that of sniffing, although biting and licking are also noted. As one moves up the phylogenetic scale to cats, the sniffing movements remain, but head movements associated with looking are also prominent. In primates a new dimension, eye-hand examination patterns, is added. These hand movements are quite specific and consist primarily of forefinger probing, pincer-like grasping, picking, palm-clasping, and hand-examining. The underlying postural-motor components are similar in all of these motor activities. An individual motor component of the searching-examining patterns can be integrated into several stereotypies and may be directed either toward external objects or toward the animal's own body (as in patterns of grooming).

Over time, the stereotyped patterns become more repetitious and more constricted. Figure 1 illustrates the gradual constriction of a cat's head and neck movements that orient the head for visual regard. Over a period of two weeks, the orienting background movements often tend to drop out, leaving a small, pecking-like movement of the head in an extremely constricted pattern, as if the cat were sniffing at a small crumb or tiny morsel of food.

Attitudes and Postures



One of the most characteristic series of changes observed in cats during the period of chronic intoxication occurred in the animal's attitude.[1] The most frequent characteristic of early amphetamine intoxication was an abnormal investigative attitude—operationally defined as actively reaching out to or approaching restricted elements of the environment, with an excessively compulsive appearance. The evolution of the stereotyped motor behavior was intimately related to the abnormal investigative attitude (figure 2) and at times this attitude would persist in a given animal even after the motor stereotypy had ceased.

Another distinctive attitude, which appeared primarily in the later days of the intoxication cycle, was the reactive attitude—characterized by sudden, disproportionate startle reactions with a jumpy, agitated quality. This abnormal reactiveness was heralded by an increase in the speed and suddenness of movements and was later accompanied by a general increase in activity and agitation. At times the animals' movements were suggestive of akathisia and dyskinesia. In the end stages of the chronic intoxication cycle, even though the animal might be in a frozen posture, sudden orienting movements toward a real or "hallucinated" stimulus were often observed. Many animals appeared to be increasingly aware of minor stimuli in their environment and acutely apprehensive about it.

This intense hypersensitivity to the environment was a dramatic reversal of the complete disregard for transient environmental stimuli that characterized the abnormal investigative attitude. Although in the end stage much of the reactiveness appeared to be oriented toward "internal" cues, there was no question that minor external stimuli often overwhelmingly impinged on the animal in a way that triggered a fearful, overreactive orienting response. A slight, remote sound in the laboratory, for ex-

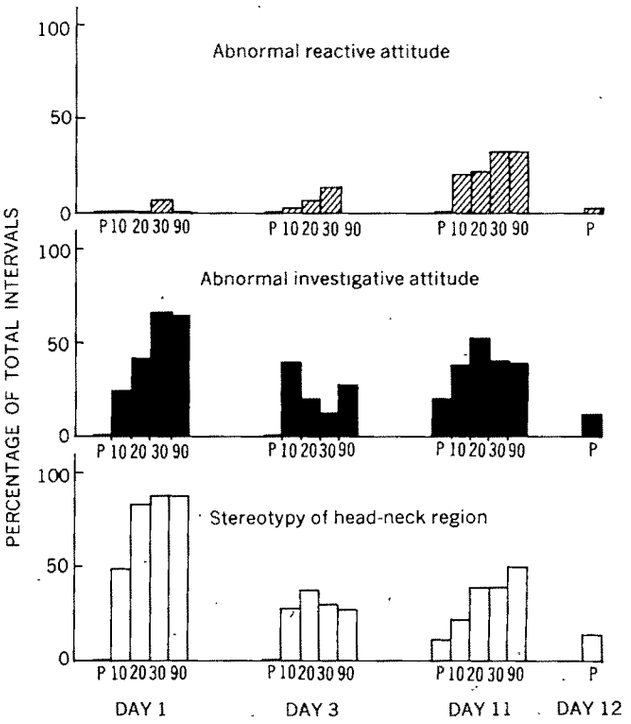
[1] In our studies "attitude" is operationally defined as body posture and activity in relation to the environment. This includes the animal's regard and reaction not only to his surroundings but also to his own body.

FIGURE 1
*Progress of the Tip of a Cat's Nose, Traced from a Slow-Motion Videotape**

*Each tracing represents 30 seconds of activity at the indicated time after the injection of amphetamine on day 1.

ample, might cause a violent turning of the head or jumping by a cat that ignored gross movements within its immediate field of vision. Or a glimpse of its own image on the shiny wall of the cage would cause a cat to jump back in apparent panic. Not infrequently a cat would jump back and turn vigorously to one side in response to a nonexistent (apparently hallucinatory) stimulus.

In the early days of intoxication, the persistent restrictiveness and directedness of the animals' behavior were reflected in their "postural-attitudinal" set as well as in their stereotyped movements. As intoxication progressed, however, there was increasing dissociation between the animals' underlying postural base and the superimposed movements and attitude. Toward the end of the intoxication period, a given animal might change his activity while maintaining the same posture—with the result that the behavior-posture relationship appeared dysjunctive and bizarre.



The last stage of intoxication was often characterized by akathisia-like repositioning and stepping movements that had the same agitated starting-and-stopping quality frequently noted in psychiatric patients with more chronic extrapyramidal manifestations induced by neuroleptic drugs. Toward the last day of the two-week study period many animals showed transient or adventitious movements that appeared to have little or no relationship to the main vector of behavior and that at times appeared incongruent to the overall behavioral configuration. The composite picture was one of hyperkinesia, in which the gradual breakdown of organized behavior accompanied an abnormally aroused and often fearful state.

DISCUSSION

Similarities Between Experimental and Clinical Amphetamine Intoxication

We have attempted to relate the progressive stages of chronic amphetamine intoxication in animals to the evolving stages of behavioral psychopathology observed in human amphetamine abusers. Because of their cognitive-perceptual nature, the symptoms most eminently related to the evolving paranoid psychosis are difficult to correlate directly with behavioral manifestations in lower animals. Remarkable similarities do exist, however, and in general it appears that the evolution of behavior in animal models is in many ways analogous to that noted in human patients. Table 1 presents our triple-layered

FIGURE 2
*Relationship Between Attitudes and Stereotypy During the Course of Amphetamine Intoxication**

TABLE 1

Triple-Layered Analysis of Chronic Amphetamine Intoxication as a Model of Functional Paranoid Psychosis

Category	Early Stages	Intermediate Stages	End Stages
Functional paranoid psychosis	Paranoid tendencies		Paranoid psychosis
Human model psychosis (chronic amphetamine intoxication)	Curiosity: repetitious examining, searching, sorting behavior	Sustained pleasurable suspiciousness: looking for meanings, minutiae	Ideas of reference; persecutory delusions and hallucinations: fearful, panic-stricken, agitated, overreactive
Animal model psychosis (chronic amphetamine intoxication)	Abnormal investigatory attitude with repetitious activity	Restricted repetitious activity	Reactive attitude

model, in which amphetamine psychosis serves as a model of functional paranoid psychosis, and chronic intoxication studies in animals serve as a behavioral model of amphetamine psychosis.

The activities of many amphetamine abusers demonstrate a remarkable resemblance to patterns of examining behavior seen in animals. For example, amphetamine-induced repetitive "grooming behavior" in human addicts is not unlike that noted in rhesus monkeys. Usually it is manifested as incessant examining, rubbing, and picking (using the forefinger probe and pincer grasp), which often result in raw blemishes and in scars. Individual patients observed through a one-way screen sometimes spend hours examining and probing visually accessible parts of the body (9).

These same behaviors demonstrate the importance of the time dimension in the formation of delusions through the gradual organization of behavior, thought, and feeling about these acute experiences. Many patients who demonstrate grooming behavior, for example, develop marked delusions of parasitosis and spend many hours examining their skin and digging out imagined parasites. These delusions appear to develop out of early sequences of skin sensations and repetitive "grooming responses." Thus, in both man and lower animals, sequences of patterned behavior, such as the grooming response, take on an autonomy and centrality of their own. In man, the next step is the gradual cognitive development of a corresponding entrenched and stereotyped delusion (1).

Although he did not recognize the common mechanisms underlying automatic-compulsive behaviors and stereotyped expressions, Bleuler (14) listed a variety of repetitive behaviors that he called stereotypies. In these he included posture, movement, attitude, and thinking. He even mentioned stereotypies of drawing, music, writing, and speech (verbigeration). Bleuler considered these constrained modes of behavior most characteristic of catatonic schizophrenia, but he noted that they were also present in other forms of schizophrenia, including the paranoid type. We have previously discussed the many features that paranoid and catatonic schizophrenia have in common and their relationship to the amphetamine psychosis (7).

We have pointed out that a common attitudinal-postural mechanism may subserve both the motor stereotypies and the constricted perceptual and cognitive patterns (7, 15). We conceive of these postural mechanisms not as passive responses providing orientation in space but more as a vigorous outgoing behavior that is acting on and projecting sensorimotor apparatus onto the environment or as reaching out and selecting parts of space and objects to be seen, felt, and thought about. Qualitatively the nature of these mechanisms might fall somewhere between posture, attitude, and initiation of movement. These mechanisms could well initiate and coordinate the many modes of perceptual attention, including searching and orientation to the outside world; conversely, these mechanisms may direct attention between various external as well as internal cognitive sets.

An amphetamine-induced loss of initiative or distortion of the mechanisms that regulate the continuous flow of behavior is postulated as the factor underlying not only stereotypies but also the perseveration of perceptual-cognitive-attitudinal sets. Thus we found in our cats fixing of attention and attitudes as well as fixing of posture and patterned movements. In other words, the animal's attentive mechanisms are persistently directed to a certain aspect or part of the environment, even after the accompanying stereotypy has broken. These fixed attitudes are not unlike those observed in speed freaks who become "hung up" for hours, either on a puzzle or in examining-sorting compulsions, or in suspicious, repetitious scanning movements of the eyes. Thus, a marked tendency to maintain attitudinal sets, as well as the accompanying examining modes, is characteristic of chronic amphetamine intoxication in both man and animals.

By the same mechanism, thinking itself could become repetitious as a result of perseveration in one of the systems subserving perception and cognition. For example, it is possible that stimulation of a specific postural-attitudinal set might not only induce the motor components of grooming behavior but also tend to constrict perception toward the enhancement of minute objects and, in this way, potentiate the associated thinking process that leads to the delusion of parasitosis. By an analogous process, the scope of the all-pervasive attitude of curiosity and/or suspiciousness that characterizes incipient

paranoid schizophrenia or the beginning phase of amphetamine psychosis might become increasingly constricted until, under the influence of behavioral disorganization, increasing arousal, and/or fear, the individual's behavior evolves into a paranoid reaction.

Neurochemical Basis for Amphetamine-Induced Behaviors

Over the past several years there have been exciting developments in research attempting to fractionate the types of behavior induced by amphetamine intoxication and to ascertain which behavioral neurotransmitters mediate these specific behaviors. It has been demonstrated that amphetamine-induced release of the neurotransmitter dopamine, which is densely distributed throughout the nigro-neostriatal system (16, 17), is responsible for the stereotyped behavior (18–20), while norepinephrine mediates the amphetamine-induced hypermotility. The nigro-neostriatal dopamine system is known to have a marked effect on the postural and motor mechanisms associated with attention—a finding that is in keeping with the amphetamine-induced behavior observed in animals as well as in man.

Recent studies on animals with unilateral, lesion-induced degeneration of the nigro-neostriatal dopamine system have demonstrated that when L-dopa or amphetamine is administered to these animals there is spontaneous turning of the head to the side of the lesion and neglect of sensory stimuli or searching behavior on the contralateral side (21). In addition, McKenzie (22) has demonstrated that bilateral ablation of the olfactory tubercle in rats markedly reduces the sniffing stereotypy induced by stimulation of the dopamine receptors. The projection of the dopamine terminals into the olfactory tubercle (23)—the old motor nucleus of the olfactory brain—also fits well with the observation that amphetamine stimulates postural changes and head movements related to olfactory searching in macrosmatic animals.

Functionally there are additional indications that the rhinencephalic forebrain is mediating the type of behavior induced by amphetamine (15). Electrical stimulation of the pyriform cortex, the olfactory tubercle, the amygdala, and the insulo-orbital cortex produces various oral exploratory activities, such as rhythmic sniffing, gnawing, and licking movements (24). In man similar automatisms and rhythmical movements are accompanied by characteristic changes in consciousness in the course of psychomotor epileptic seizures. We have previously reported (15) that there is a dramatic similarity between the psychosis associated with temporal lobe epilepsy and amphetamine psychosis. Recently we have demonstrated that, following the blockade of norepinephrine synthesis, amphetamine induces a dramatic increase in rhinencephalic electrical activity, with subsequent seizures (25). More importantly, this catecholamine manipulation produces behaviors (e.g., reactive attitude) that are seen only at the end stages of chronic amphetamine intoxication.

In addition, it is now well known that haloperidol and pimozide, two drugs that primarily block dopamine receptors (26), are two of the most effective antipsychotic agents currently in use. Angrist and associates (27) have also demonstrated that d-amphetamine is only one to two times as potent as l-amphetamine in producing psychosis although the ratio of potency is 10:1 for other effects. This potency ratio for the elicitation of psychosis is quite consistent with the hypothesis of stimulation through dopaminergic mechanisms since there are similar dose-response relationships in producing experimental animal stereotypy (28) and in changing the comparative kinetics of the accumulation of norepinephrine and dopamine at synaptasomes (29).

Fuxe and Ungerstedt (30) have previously demonstrated that amphetamine-induced behavior is related not only to the type of catecholamine neurotransmitter activity, but also to the ratio of norepinephrine to dopamine. By appropriately blocking and stimulating norepinephrine and dopamine mechanisms, they demonstrated that a strong norepinephrine-to-dopamine ratio is associated with exploratory locomotor behavior; when the ratio is reversed, an exploratory stereotypy is produced. When norepinephrine is depleted and, in addition, dopamine activity is enhanced by the administration of L-dopa, the exploratory stereotypy becomes highly constricted and compulsive. Gunne and Lewander (31) have demonstrated that *acute* amphetamine intoxication in animals primarily depletes norepinephrine, whereas *chronic* amphetamine intoxication depletes both norepinephrine and (to a lesser degree) dopamine.

When both norepinephrine and dopamine are depleted, important behavioral effects are induced through loss of the righting reflexes (32), and the catecholamine receptors become supersensitive to such receptor stimulants as apomorphine (21). Thus catecholamine depletion may be quite important in setting the stage for a supersensitive response to amphetamine. It may be that the depletion of norepinephrine and/or dopamine, as well as the disturbance of the balance between the two neurotransmitters, may have so sensitized the catecholamine neurons that additional amphetamine stimulation produces the hyperreactive state observed in our cats both in the later stages of chronic amphetamine intoxication and following the blockade of norepinephrine synthesis.

In conclusion, it is important that the amphetamine psychosis be regarded as an *evolving* sequence of behaviors that appears in several stages and cannot be explained on the basis of a single neurotransmitter effect. The physiological as well as the behavioral state is qualitatively different in the various stages of chronic amphetamine intoxication. Thus, in the model psychosis based on chronic amphetamine intoxication, the effect of the drug in further stimulating the altered psychological state of an animal resulting from previous intoxication, as well as stimulating depleted supersensitive norepinephrine and/or dopamine neuronal systems, is qualitatively different from the effect of the drug on a naïve animal. This line of reasoning is consistent with our thesis that each evolving behavioral state of amphetamine psychosis provides a base for the subsequent manifestation of the psychosis.

The Dream-Protein Hypothesis

BY ERNEST LAWRENCE ROSSI, PH.D.

Recent studies of learning and memory indicate that new experience is encoded by means of protein synthesis in brain tissue. The author reviews the literature on diet, nutrition, dreams, and REM sleep and finds support for the hypothesis that dreaming is a process of psychophysiological growth that involves the synthesis or modification of protein structures in the brain and that serves as the organic basis for new developments in the personality. The author outlines a series of experiments to further test the validity of this hypothesis. The implications of this research for a "growth" or "psychosynthetic" orientation in psychotherapy are discussed.

RECENT RESEARCH in the biology of learning and memory typified by the work of Hyden (1) indicates that new learning and behavior are encoded in the synthesis and/or modification of protein structures in brain cells. This statement of the relationship between biochemical events (protein synthesis) and behavior (new learning) is sufficient for behavior therapy but the language of psychodynamic psychotherapy requires the inclusion of phenomenological events. The relationship between phenomenological events and behavior is explored by the traditional methods of psychiatry and psychology (clinical interview, psychodiagnostic testing, etc.) but thus far the relationship between biochemistry and such events as dreams and fantasies has received little theoretical formulation or empirical support. This suggests the need for a dream-protein hypothesis: dreaming is a process of psychophysiological growth whereby dramas played out on a phenomenological level involve the corresponding synthesis and/or modification of proteins in the brain; this synthesis serves as the organic basis for new developments in the personality.

Studies that support the dream-protein hypothesis can be drawn from the vast body of research that uses rapid eye movements (REM) as the index of dreaming. These involve both the relationship between protein synthesis and dreaming and the relationship between dreaming and new developments in the personality.

Dr. Rossi is Extension Instructor, Department of Social Sciences, University of California at Los Angeles, and an analyst at the C.G. Jung Institute of Los Angeles; his address is 10486 Santa Monica Blvd., Los Angeles, Calif. 90025.

The author wishes to acknowledge the assistance of Ms. Jo Ann Boorkman, Computer Search Analyst, UCLA Information and Biographical Service Section, in obtaining a portion of the references for this paper through MEDLARS Computer Search no. 101726/R001, which was subsidized by the National Library of Medicine.

PROTEIN SYNTHESIS AND DREAMING

A MEDLARS computer search covering the research literature from January 1969 through June 1972 on the relationship of diet and nutrition to dreams and REM sleep yielded 181 citations, of which about 20 percent dealt with the relationship between protein synthesis and dreaming. The most direct evidence for this relationship in humans is the finding that alterations in protein metabolism achieved by either blocking or supplementing amino acids in the diet has an effect on dreaming. It has been found by Lester and colleagues (2), for example, that low-phenyl-alanine-tyrosine diets result in a systematic reduction in REM sleep. They then found this effect could be reversed so that the percentage of REM sleep was increased when tyrosine (in capsule form) was added to the diet. Furthermore, it has been found by other investigators (3) that tryptophane has a small but statistically significant effect in increasing REM sleep. The deprivation or supplementation of amino acids that are associated with ribonucleic acid (RNA) and protein synthesis is thus directly related to REM sleep in humans.

Our literature search turned up many more references to experimental work with animals than with humans. The general finding documented by numerous animal studies (4–7) supports the finding of the studies with humans, i.e., that deprivation or supplementation of amino acids in the diet results in corresponding effects on REM sleep. In no case, however, was there a study designed specifically to evaluate this relationship. Most of the studies were motivated by interest in the neurochemical origin of REM sleep, the role of amino acids in the transmission of the nervous impulse, or the action of monoamine oxidase inhibitors on REM sleep, rather than by the concept embodied in the dream-protein hypothesis. Although the results of these studies are all in the direction that would be predicted by the dream-protein hypothesis, new studies specifically designed to test the validity of the hypothesis are now called for. Three general approaches to validating the dream-protein hypothesis seem possible.

1. In table 1, the three-stage process in the synthesis of proteins from amino acids and RNA is outlined, together with a listing of some of the metabolites and chemical agents that have been used (8, 9) to facilitate or retard each stage in learning and memory experiments. In general the dream-protein hypothesis would predict that agents that facilitate any stage of protein synthesis would tend to increase REM sleep, while those agents which block a stage of protein synthesis should decrease REM sleep. This prediction has been amply verified at the

amino acid stage but not at stages closer to the synthesis of RNA and proteins. Such verification would be needed to further confirm or disprove the dream-protein hypothesis.

2. During the past decade, innovations in biochemical analysis that permit the isolation and measurement of extremely small amounts of macromolecular RNA, of such enzymes as cholinesterase (10), and of neural growth factors (11) have enabled researchers to determine how these substances affect memory and learning. In essence these studies indicate that new developments in learning and behavior may be associated with changes in the synthesis and/or structure of RNA. If researchers can now detect changes in the presence of RNA, cholinesterase, or neural growth factors at the locus of dream activity (e.g., the visual cortex) during the REM state, they will have provided further support for the dream-protein hypothesis.

3. The relationship between protein intake and dreaming has been more difficult to describe. Although extreme protein deprivation does result in EEG abnormalities (2), I have not yet found any studies dealing directly with the relationship between the deprivation of protein or protein precursors (apart from the amino acid studies cited above) and REM sleep. Three types of research could clarify this relationship: 1) neuroanthropological studies of the effect of extreme protein deprivation on the REM sleep of population groups that are subject to these specific types of malnutrition (12); 2) REM studies on people who subject themselves to macrobiotic diets that are deficient in proteins (my preliminary interviews with a number of such people yielded the expected subjective report of decreased dreaming or dream recall while they were on such diets); and 3) animal studies that relate protein and amino acid deprivation to REM sleep (13).

TABLE 1
Agents That Have Been Used to Facilitate or Block Protein Synthesis

Item	Increase Uptake or Synthesis	Block Uptake or Synthesis
Amino Acids	Dietary amino acids: tryptophan, tyrosine, etc.	Amino acids restricted
RNA	Yeast RNA, malononitrile, magnesium pemoline (?), soluble RNA	8-azaquanine, actinomycine-D
Protein	Dietary proteins, malononitrile (dimers and trimers)	Restricted diets, puromycin, puromycin amino nucleoside, cycloheximide

DREAMS AND PERSONALITY DEVELOPMENT

Just as Snyder (14) has organized many of the diverse and apparently unrelated findings of REM research into an evolutionary theory of dreaming on the phylogenetic level, we may also apply the findings of much REM-related research to the ontogenetic development of the individual's personality. I shall summarize those findings which bear upon the integrative or psychosynthetic functions of REM sleep that are most directly relevant to the dream-protein hypothesis.

1. Dreaming is initiated and primarily regulated by internal brain processes rather than by external stimuli from the environment (15). That is, dreaming is a process that is important for internal developments within the brain itself rather than for handling external stimuli. In an evolutionary theory of dreaming, Snyder expressed this conception well:

> [The REM state] is not a condition of partial arousal intermediate between sleep and waking, but now appears to be among the most extraordinarily intense activations yet discovered in the normal functioning of the central nervous system. Although similar in many respects to highly aroused waking, there are good reasons for thinking that the functional organization of central nervous activity is quite different from waking, and that the stimulus which originates this activation is intrinsic to the brain itself (14, p. 123).

Meissner (16) has outlined the neurophysiological mechanisms characteristic of REM activation that "suggest that the striking activation of limbic structures in rhombencephalic sleep has a specific integrative function which serves to maintain the effective organization and integration of emotional and cognitive experience." The conclusion therefore seems inescapable: the state of dream consciousness concerns the organization and synthesis of internal data (e.g., personality development), while the awake state of consciousness deals primarily with the processing of external sensory data from the environment.

2. The REM state occupies up to 50 percent of the sleep time of neonates and children (at ages when learning and personality formation is greatest) and then decreases to 20 to 25 percent with increased age, as the capacity for new learning and personality growth becomes relatively less (17).

3. Recent studies (18) of the dreams of children and adolescents indicate that the typical dreams of normal children revolve about recreational activities and as such "appear most simply to represent extensions of the child's waking ego impulses to exploration and manipulation of the environment." The REM state can thus be understood as a period during which internal programs are being synthesized and consolidated so they can later be actualized in personality and behavior change.

4. Dement and associates (19) have recently summarized findings from their laboratory which demonstrate that REM sleep is necessary for the optimal control and integration of drive systems (aggression and sex) in laboratory animals even though it is not necessary for life itself. Recently Hartmann and his co-workers (20) have concluded from studies with humans that "psychic pain or psychic disequilibrium with changing defense patterns" are associated with an increase in REM sleep. The

subject who required more REM sleep "is relatively anxious and depressed, and his life style involves change and worry." These conclusions are exactly what one would expect if dreams had a psychosynthetic function in maintaining the growth and stability of the ego, since more REM sleep would be required during periods of more active personality growth, change, and stress.

5. Recent studies of the correlation between REM sleep and the process of change in psychotherapy provide interesting confirmation for the above. Freedman and associates (21), for example, reported that "striking and consistent correlations were discovered between the length of the fourth dream period and the [psychotherapy] session variables of self-satisfaction, wish fulfillment, elation, and control." I have discussed elsewhere how these types of variables can be understood as indications that a process of psychological growth (psychosynthesis) is taking place (22). This type of study thus tends to confirm that there is a direct relationship between dreaming and personality growth as stipulated by the dream-protein hypothesis.

PSYCHOTHERAPEUTIC IMPLICATIONS

Validation of the dream-protein hypothesis would provide a biological basis for modern theories of personality change, growth, and development. Most workers have been so overwhelmed by Freud's concept of psychoanalysis that they have tended to overlook psychosynthetic processes. Just as the biochemical basis of life may be conveniently divided into anabolic and catabolic processes, so one may posit a dynamic equilibrium within the phenomenological realm between psychosynthetic processes (whereby entirely new and more complex psychological experiences are created) and analytic processes (whereby a breakdown of inner experience into simpler parts is evident).

The growth or psychosynthetic orientation is actually the common denominator of a very wide range of the apparently diverse "schools" of psychotherapy that have developed since Freud (23). Apart from the ideas of such early ego psychologists in the Freudian psychoanalytic framework as Hartmann, Kris, and Lowenfeld, Jung's central concept of individuation, Adler's concept of the creative self, and Rank's emphasis on the artist-type may all be understood as efforts to explore the synthetic or creative aspects of personality development. The existential approaches of Binswanger, May, and Frankl emphasize the complex coping methods by which a person actually creates his existence and world view. In recent years the client-centered, humanistic, and gestalt psychologists have all elaborated approaches and attitudes toward psychotherapy that focus on a growth orientation.

While the growth orientation frequently has been presented in a global and loosely defined manner by many of these theorists, the psychosynthetic approach of Assagioli (24) and the autogenic meditation methods of Schultz and Luthe (25) have introduced a certain degree of precision and scientific control in facilitating personality development. Assagioli, for example, has pioneered in the development of "meditation" methods by which the patient allows his imagination to elaborate a standard series of emotionally significant patterns of internal imagery. This elaboration of internal imagery may have important diagnostic significance; more importantly, however, the growth-oriented therapist uses this approach to facilitate the actual synthesis of new psychic structures that can become the nuclei for new developments in the personality. I have recently extended this approach by illustrating in detail how symptoms of "psychopathology" can be understood as breakdowns in the natural processes of personality development (22). This analysis of these psychosynthetic processes, as outlined in a series of "phenomenological equations," suggests how they may be used to develop further approaches to facilitating personality development in psychotherapy.

The obvious drawback of the phenomenologically oriented growth approaches to psychotherapy is that they lack the foundation in biology and chemistry that most workers since Freud consider so important for any psychodynamic psychology. Concepts of libido, genetic determination, hormonal regulation, imprinting, and most of the other current variables of biological psychiatry are sometimes useful in dealing with the global or molar aspects of personality but they are obviously unable to account for the intricate variability found in individual fantasies and dreams that continually change with life experience. The dream-protein hypothesis is a means of directly relating these subjective events of personality growth to biochemical events. If the dream-protein hypothesis can be further validated it would be a major step in establishing a biochemical foundation for personality dynamics.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1974. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or any other work, including audiovisual presentations, submitted to or presented at any professional meeting or published during the year ending December 31, 1973. The award, which includes an honorarium of $250 and a plaque, will be presented at the Convocation of Fellows at the annual meeting in Detroit, Mich., May 1974.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Jonas Rappeport, M.D., Chairman, Guttmacher Award Board, American Psychiatric Association, 1700 18th St., N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is January 1, 1974, and to be considered any entry must be in Washington by that date.

Indian Education: A Human Systems Analysis

BY CARL A. HAMMERSCHLAG, M.D., CLAYTON P. ALDERFER, PH.D., AND DAVID BERG, M.A.

The problems of Indian boarding schools are examined in the light of both systems theory and data from interviews and questionnaires conducted at one school. The authors conclude that the schools have failed to define their primary task—to educate or to handle children with behavior problems. More importantly, the impact of the whole educational system perpetuates the Indians' powerlessness and dependency on the government. The authors express the hope that, if there is more community involvement in the schools, this will lead to greater assumption of responsibility by Indians in other spheres.

THE BUREAU OF INDIAN AFFAIRS (BIA), charged with the education of American Indians, today operates more than 200 schools in 17 states. Of the approximately 200,000 school-age Indian children, 35,000 are in BIA boarding schools, 16,000 are in day schools, and 24,000 are housed in BIA dormitories while attending public schools. Of the 35,000 children in boarding schools, more than 12,000 attend off-reservation boarding schools, which for the most part provide a high school education for Indian children who have completed the eighth grade. The remainder are in on-reservation boarding schools; 8,000 of these are elementary school students, nine years old or under (1). Enrollment in BIA boarding schools is increasing; indeed, it has doubled in the 1960s.

The history of the boarding school experience, its inadequacies, and its archaicisms were first commented upon by Merriam in 1928 (2). Studies since have concluded that, as the cultural and educational backgrounds of Indian children become more like those of white children in public schools, the educational achievement of Indian children will more closely match that of white children (3–5). To many Indian people that implies a not very subtle attempt to sow the seeds of cultural dissolution, to use the schools as an instrument of Indian cultural annihilation. There are still rituals among tribes today to cleanse their children of white contamination on their return from boarding schools. This study explores the impact of a boarding school system on both students and staff members who live, learn, and work there.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Hammerschlag is Mental Health Consultant, Indian Health Service, 4212 North Sixteenth St., Phoenix, Ariz. 85016. At the time of this study, Dr. Alderfer and Mr. Berg were both with the Department of Administrative Sciences, Yale University, New Haven, Conn., where Dr. Alderfer is Associate Professor and Mr. Berg was a graduate student.

THE SCHOOL SYSTEM

The school studied, located in a major southwestern urban setting, has approximately 700 students, aged 14 to 22 years, and 200 staff members. All the students are Indians; most of the teaching and administrative personnel are non-Indian. At least 60 percent of the student body enters this boarding school for so-called "social reasons," which include extreme poverty, large families, language difficulties, and behavior problems in other schools. Because so many children come to the school for these reasons, there is considerable ambiguity among the staff as to whether the primary mission of the school is one of behavioral control or teaching.

For example, the dormitory attendants, who are charged with the management of 120 students per dorm, see their jobs as maintaining order and resolving immediate crises. The teaching staff see their roles as instructional, but students who do well in class are not necessarily the ones who also behave well outside the classroom. There is little interpenetration of the boundaries between these distinct task groups at any time. When it does occur, it usually concerns decisions about the dismissal of students with behavior problems. If the greatest articulation of structure exists for a secondary task of the system (such as behavioral control) and the purported primary task (i.e., education) remains isolated, the system is in trouble.

The concept of boundary is an aspect of open systems theory that treats organizations as systems whose survival requires the continuous exchange of materials with the environment (6–8). If the boundary is too permeable it invites inundation, chaos, and disorganization, whereas an impermeable boundary becomes a barrier that causes death through entropy. There are boundaries that separate the organization from its environment and those which are internal to the organization. These internal boundaries separate task systems from each other. The authority for these separate internal operations (dorm, teaching, guidance) is delegated by top management to subordinates. The viability of the subsystem, and ultimately of the total organization, is dependent on successful boundary transactions between these adjacent subsystems.

In the school's case, each subsystem functions as if it were totally independent and involved in tasks that are perceived as mutually exclusive. For example, a dormitory head telephoned a guidance counselor at midnight to say that a student was drunk and disorderly and asked that he come over right away. The counselor replied, "I don't think I can do much counseling with the student in

her condition." The dorm head exasperatedly shouted, "I want you here; I want you to see what we have to put up with," and then hung up the phone. The event is illustrative of a broader theme, one that has less to do with students and more with the feeling that each internal subsystem has little sensitivity to and understanding of what the other does.

The theme of impermeability of boundaries, expressed in issues like territoriality and insensitivity, occurs not only between adjacent subsystems but also internally within each task group—between dormitory heads who interpret and enforce restrictions differently ("I think the rules for boys' and girls' dorms should be different"), between academic departments ("This should be a vocational training center, not a college prep school"), and between each staff and its supervisor ("I don't know what the assistant principal in charge of my department is really supposed to do").

Finally, the boundaries between the school and the external environment (local community, Indian reservations, Washington, D.C.) affect and reinforce such internal organization perceptions. The external boundary regulation is much less delegatable than internal task functions, and it becomes the major task of top management. For example, the school's top management was recently confronted by pressure from the community and from Washington to keep children in school and was forced to make a decision to have proposed expulsions reviewed by a board including representatives from the tribe, family, school, and central office. The distances some of these representatives would have to travel makes such gatherings difficult, nor is there much agreement once they are convened. This has made it virtually impossible to obtain approval for expulsions. Since the internal task groups had used the threat and actuality of expulsion to enforce behavioral conformity, this policy on expulsions (in which the school itself had no input) removes whatever disciplinary power the task groups may have had. As within the internal subsystems, the exclusiveness and impermeability of boundaries results in isolation and resentment. Although it is said that all subsystems work toward one end, the basic theme—impenetrability, not working together, and failure to define tasks—is continually reinforced. By neglecting the boundary tasks and its role tasks, a system is produced that then tends to become, as will be seen, stagnant and incapable of growth.

METHOD

One of us (C.A.H.) was introduced as mental health consultant to the Phoenix Indian High School in July 1970 with the understanding that he would be spending approximately half his time there. He expressed his interest in children and desire to serve as an organizational consultant, as well as his hope and expectation that he would be able to work with the school community to define his role. As a way of getting to know more about the school and the issues people felt were important there, a series of in-depth interviews was conducted. A representative cross-section of all departments and students was seen and, with their consent, the interviews were recorded. The formally outlined interview included wide latitude for discussion of individual items of special relevance. On the basis of those interviews and subsequent replays, several general areas of concern became apparent. A questionnaire based on those shared concerns was developed so that the entire school community could respond to those commonly perceived problems. The questionnaire was distributed three weeks after the start of school; it was subsequently computerized and evaluated. These initial data were shared, discussed, and evaluated by the entire school during a two-day feedback session in March when formal classes were suspended.

To get some sense of what happened to people the longer they remained at the school, and to discover differing perceptions as a function of time within the system, the questionnaire was redistributed in the late spring of 1971. Similar data analyses were run and the results were compared. The main focus of this paper is the school as a social system, but the questionnaire data deal with individual attitudes. In interpreting the data, therefore, we have drawn from fieldwork talks, observations, and experiences to bridge the gap.

RESULTS

The BIA's guiding educational philosophy "encompasses the belief that all Indian children must have the opportunity to realize their full potential and to become useful members of society." It suggests that to facilitate ongoing and independent learning teachers should have access to widespread and well-organized materials and services. They should bend their energies toward developing attitudes of discovery, problem-solving research, and experimentation leading to creative and critical thinking.

Yet in spite of such expectations, considerable differences exist in terms of what people at the school think is being learned. In responding to the item "I use my abilities in my academic subjects," both students and teachers agreed that the longer they stay in school the less likely they are to use their abilities. Apparently something happens so that both students and teachers stop learning. There is also strong agreement between students and staff members that as one stays at the school one finds that it is really too easy to get passing grades. This raises the interesting possibility that both students and teachers may stop learning when they realize that no matter what happens in the classroom everyone passes anyway, thus removing the impetus for students to work and teachers to teach. In addition, students in the junior high grades feel that they are being well prepared for college, but those who remain to become upper classmen begin to share the staff's perception that they are being poorly prepared for college work (see table 1).

Replies to the item "Students who come here really don't want to learn" indicated that students and staff

Junior students	30	32
Senior students	28	20
Academic teaching staff	0	76
Vocational teaching staff	0	75
Dormitory staff	5	52

members agreed (and more so as time goes on) that students do not really come to the school wanting to learn. Do students who remain at school to become upper classmen not want to learn, or do the students fulfull institutional or staff expectations that they cannot learn? Are students poorly prepared for college because they do not use their abilities or because the subjects are too easy?

Merton, in proposing the idea of the "self-fulfilling prophecy," stated that in many situations people tend to do what is expected of them. That phenomenon was recently vividly documented by Rosenthal and Jacobsen, who showed that student performance is affected by the teacher's expectations (9). The teacher who assumes that her/his students cannot learn discovers that she/he has a class of children who are indeed unable to learn; another teacher who makes the opposite assumption may discover she/he has a class of interested learners. (A similar process applies to other forms of behavior as well.) Charles Silberman, in *Crisis in the Classroom*, noted that "one cannot spend any substantial amount of time visiting ghetto schools, be they Black, Puerto Rican, Chicano or Indian, without being struck by the modesty of the expectations teachers, supervisors, principals and superintendents have for the students in their care" (10).

Using our own data to illustrate, is it possible that the students feel they do not come here to learn because, in spite of being at school, their teachers do not believe they are being well prepared? Teachers who give passing grades easily, but at the same time do not believe the grades reflect the child's ability or preparedness, are really saying the grade is not worth much; it is not a reflection of what the student does or ought to know. Doing well at the Indian school academically does not mean students will do well elsewhere. Indeed, it is the staff's expectation that they will not; the students know it, and they begin to believe that they are responsible for it. The school continues to have difficulty with dropouts, act-outs, and apathy because its students believe that it does not pay to achieve and do well in school. School holds a false promise: you can become all you want by learning, but no one believes you are learning.

It becomes clear in many ways that students and teachers talk to each other but do not really hear one another. Eighty percent of the students say that they often say things in their Indian language to annoy the teacher, but only 40 percent of the teachers perceive that it is happening at all. Students agree two or three times as often as staff members (and more so as the year goes on) that teachers are too old and have been here too long to be good teachers. The teaching staff too begin to agree with that perception as the year goes on. It is not only students who fulfill the teachers' expectations, but the reverse as well. The evidence suggests that the concept of the self-fulfilling prophecy ought to be expanded. Students and teachers seem to collude to develop negative expectations of each other, which each then proceeds to fulfull. The result is that neither teachers nor students develop; both

become estranged, do not use their full abilities, and fail to grow and perform together.

INDIANNESS AND POWERLESSNESS

All who were interviewed seemed to agree that whether one is or is not an Indian made a difference in terms of one's experience at the school. Although all people at the school agreed that their respect for Indian heritage and tradition increases as a result of being there, it is difficult in some ways to translate such respectfulness into objective terms. It is the Indian student or staff member who hears, with far greater frequency, insulting things being said about Indian people. The saying of such things and the hearing of them increases as the school year goes on.

Indian students and staff members agreed about twice as often as the non-Indian staff that "it is impossible for a non-Indian to appreciate what it means to be an Indian" (table 2). Most striking is the fact that it is the Indian staff, even more than the students, who, as time passes in the school, perceive their Indianness as something that separates, distances, and devalues them. It is they who are most disenfranchised and powerless within the system.

Much has already been written and said about the uninvolvement and powerlessness that students feel and experience in school settings (11–14). They are uninvolved in the one-way learning street, where teachers reveal the proper, orderly, laddered acquisition of facts in an unenthusiastic way. Less emphasis has been placed on the fact that in many ways school staff members mirror the students' feelings. In this school, it is the Indian staff member who perceives himself as the least able to change things, the least in control, and the most disaffected (table 2). It is the Indian staff member who changes most dramatically with time; the longer the staff members remain at the school, the less likely they are to describe themselves as able to change things. They feel increasingly powerless (table 2). The converse is true for non-Indian employees who, as they spend more time in the system, see themselves as more able to change things at the school.

Such perceived powerlessness leads to disaffection. On the item "If I could I would send my children to school here," the responses of the Indian staff members changed most dramatically as the year went on; they became the group least likely to send their children to this school by the time school ends (table 3). Similarly, it was the Indian staff who changed most dramatically in terms of their involvement in the school (table 3).

Slightly more than half of the BIA's 160,000 employees are Indian; most of these fill the lowest ranks (janitors, aides, drivers, laborers, secretaries); 80 percent of the better jobs are held by non-Indians. Even in nonprofessional areas, Indians for the most part are not in supervisory roles and they are the ones who are most dependent upon the system since they have the fewest realistic options for work elsewhere. Even students, who may be ruled, restricted, and structured, know that their time at school will end. Indian staff members are a captive audience who, because of their lack of proper credentials and thus salable skills, may stay indefinitely. And it is not the staying that is painful but the sense that even though they stay nothing will change. In the face of such a dilemma, one becomes disaffected, disenchanted, and dissatisfied, but rather than act out these feelings (which students sometimes do), Indian staff members tend to become apathetic and unfeeling.

CONCLUSIONS

Although there have been reforms in Indian education, the schools themselves remain far less effective than is desirable. The BIA's educational goals emphasize a system in which people share and grow and a setting in which student and teacher share what one wants to know and the other wants to teach, in which there is less submission to an obligatory curriculum and a greater number of options, and in which there is less emphasis on externally applied controls and more on one's responsibility for

one's own behavior. Simultaneously, however, the boarding school invites those with "behavior problems which cannot be solved by families or existing facilities" and who can "benefit from the controlled environment of a boarding school." It cannot do both.

By accepting students for "social reasons" it implies that it can deal with them in some way. It has not and, because it has not, it demoralizes both teacher and student. In accepting the role of agent of social control, the school overreaches its resources, leaving precious little time for scholarly endeavors. Since they are unable to deal with students who act out and drop out, the staff members begin to wonder what they are doing here; they eventually withdraw and simply survive from day to day.

In systems terms, the school fails to define its primary task. The subsystems operate as if they exist only to serve their individual ends. Their inability to articulate, to make their boundaries more permeable, and together to more clearly define the primary task is expressed in frustration, powerlessness, and ennui.

Interestingly, the school is being asked to deal with problems that are based on a 100-year history of paternalism and its concomitant tribal dependency. The more the school accepts the charge of dealing with "problem" children, the more it deemphasizes the real need for it to be dealt with elsewhere, by parents and by the tribes themselves. It is the people who can and must assume some power in determining their futures rather than abandon that responsibility to others. Since the system has, for a century, forced and encouraged such dependency, any self-steering behavior has become difficult. But the more the school permits itself to be used as an institution for control, the more it reemphasizes and tacitly encourages the tribes not to deal with it. The *giving* of education, like the giving of health and welfare, destroys people by robbing them of their own sense of powerfulness and worth. It reemphasizes the institution's ability to give and the people's need to receive; it thus recreates a master-slave syndrome (15).

This is clearly a long way from a simple discussion of Indian education. Yet if the concern is with education one cannot restrict one's observations only to the schools. To study Indian education means to study Indian history and American society and to understand that the difficulty in the education of Indian children lies as much with a society that has degraded and disenfranchised Indian people for more than a century as it lies with the teachers, students, and schools.

The recommendations offered so far have included making the off-reservation boarding schools into residential treatment facilities for seriously disturbed Indian children. It has also been suggested that personnel be increased, that there be more representative and involved school boards, and that parents become more involved in the establishment of the curriculum. In the face of massive tribally perceived powerlessness and institutional entrenchment, these solutions, as they relate to existing boarding schools, are trivial. The boarding schools are ineffective educationally and they are ineffective as agents and enforcers of social control. They perpetuate, by mere virtue of their existence, the myth that they can educate and control better than parents and communities can. Most importantly, by being available they remove the impetus for those issues to be dealt with directly by the tribes themselves. The answer must lie in public education, with active community involvement in all aspects of decision making. Such an excercise in visible power would serve as a model for the assumption of similar responsibilities in other spheres of reservation life. From the limited context of schools, perhaps we can begin to minimize the rampant institutional dependence that pervades most tribes.

The Eclectic Approach to the Treatment of Phobias

BY K. ROY MACKENZIE, M.D.

A patient with air travel phobia was treated by a variety of therapeutic techniques. Initially, intensive reciprocal inhibition similar to implosion therapy was used, with concomitant supportive psychotherapy. Then psychodynamically oriented short-term therapy was introduced to achieve more lasting results. The author suggests that rather than establishing a dogmatic position in terms of selected technique, the therapist should take a truly eclectic approach within the unfolding treatment of a single patient.

TECHNIQUES of behavior modification based on learning theory have been increasingly used by psychiatrists in recent years. This has been particularly true in the treatment of phobias. Most psychiatric residency programs include behavior therapy training in their curriculum and emphasize the need for eclecticism in the choice of treatment modality.

Despite these trends the choice of a behavior therapy program is often accompanied by a lingering regret that more "respectable" psychotherapeutic principles could not be used. On occasion, the decision to use behavioral approaches is accompanied by the requirement for referral to a specialized practitioner or by the downgrading of the status of the patient. These attitudes imply to the patient that he is being abandoned to the vagaries of a new and dubious therapeutic modality and that if it does not work he can always return to the tried and tested halls of traditional psychotherapy.

This paper suggests that the truly eclectic practitioner will be prepared to incorporate different treatment modalities within the confines of treatment of a single patient. The following case report and discussion center around the use of concepts borrowed from implosion therapy, reciprocal inhibition, supportive psychotherapy, and brief psychodynamic psychotherapy.

CASE REPORT

A 50-year-old professional man presented himself for treatment with an increasing level of anxiety that was reaching almost intolerable proportions. His anxiety revolved around a proposed trip to Europe in two weeks. He had almost decided to cancel the trip despite the disappointment it would mean for his wife and children.

For many years the patient had enjoyed flying and had even done considerable flying in small planes with friends who were recreational pilots. Six years prior to this visit he had been at a professional convention in a distant city and had developed first a sore throat and then a peritonsillar abscess. He deferred obtaining treatment there, and on the three-hour plane flight home he noted the rapid onset of laryngeal edema, which produced early symptoms of obstruction of the airway. He was aware of the possible implications of this condition and became severely anxious.

Since that time he had felt marked apprehension over taking an airplane flight. He had taken flights on two occasions, under great duress and with marked anxiety, but had canceled numerous trips at the last minute because he could not face the prospect of entering the plane. He had flown most recently about 18 months prior to his present illness but had felt so much anxiety while away that he terminated his visit and returned prematurely.

His specific fear of flying had generalized to a concern that he would not know where qualified medical services were available. When discussing a proposed flight, he talked of airports where emergency landings could be made and of his knowledge of hospitals and physicians along the route. The degree of his anxiety was directly related to the distance traveled. A trip of 75 miles would produce definite anxiety, but a trip of 200 miles would probably be canceled. A 500-mile trip would precipitate a major crisis, and anything beyond that would hardly be countenanced. While the patient was away from home the slightest physical symptom, such as a dry throat, would trigger an anxiety state over impending illness.

He had promised his family the European trip in a moment of impulse, feeling that perhaps by having a definite objective he would overcome his fears. He had come to regard his phobia as a sign of weakness and incompetence that was seriously undermining his previously healthy sense of self-confidence. He felt that he would be incapable of handling an unexpected or crisis situation and therefore would have to suffer the loss of respect of his family.

A detailed history did not reveal evidence of major psychopathology in other areas of his life. His work demanded intense, limited concentration. He became annoyed at minor delays and inefficiencies in his staff, but these characteristics had made him an effective worker, and he was regarded as a well-qualified person in his profession. He was happily married and had a satisfactory sexual adjustment. His four children, who ranged in age from 13 to 22, were adjusting satisfactorily, although his oldest son tended to be overly compulsive about his studies and was somewhat insecure over his progress despite achieving superior grades. These characteristics were similar to those of the patient when he had been a student. The patient had always found it difficult to relax from his work and tended to place himself under unnecessary responsibilities. He had not been one to take

Based on a paper read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972. The original title of this paper was "Behavior Therapy Versus Psychotherapy in Phobias."

Dr. MacKenzie is Associate Professor of Psychiatry, University of Calgary Medical School, and Director of Psychiatry, Holy Cross Hospital, 2210 2nd St., S.W., Calgary, Alberta, Canada.

vacations and when he did so usually wanted to get back to make sure everything was operating satisfactorily at the office. Despite this, he had a good relationship with his four children and had an active social life with many friends.

The patient was given 5 mg. of diazepam orally at the beginning of the initial treatment session, which lasted three hours. Relaxation exercises were used. The patient proved adept at these, and a light hypnotic trance was easily induced. A process of hierarchical desensitization was undertaken. He was asked to imagine scenes in the following sequence: taking a short trip with his family in the countryside a few miles from the city, taking a longer trip to a resort community 90 miles away, driving past the airport, driving into the airport and sitting in the lounge, sitting in the passenger waiting area, boarding the plane and looking around, sitting in an airplane seat, feeling the plane move down the runway, taking a short commuter flight lasting half an hour, taking a longer flight to a city one hour away, and finally, taking the proposed overseas trip. The session ended with a posthypnotic suggestion that the patient relax while seated in an airplane.

The patient was then instructed to go to the airport directly from the office and take a 25-minute commuter flight to a nearby city. He was instructed to call me from the terminal at the other end and report his progress, which he did. He took an immediate return flight and again called me upon his arrival. During both phases of this trip he was able to relax and experienced little anxiety.

The patient was seen on four other occasions over the subsequent two weeks. He was able to keep his anxiety under control through a combination of posthypnotic suggestion, the use of a relaxation tape, and 5 mg. of diazepam three or four times daily. Five days prior to departure a minor crisis occurred when he received word that he had some income tax arrears to pay. He pleaded that this would be a major financial burden and that he would not be able to finance his European trip. Since there was an element of validity to the argument, despite his use of it for psychodynamic ends, it was suggested that the family have a meeting to discuss the situation and that they should in any case make an extended trip, even if not overseas. Two days later he returned to say that he had found himself increasingly annoyed at capitulating to his anxiety. He had decided to obtain a loan to finance the trip. He was clearly in much better control and was occupied with the realistic problems of preparation for the trip. His oldest son was seen and given a brief description of the self-reinforcing nature of phobias and of the need for firmness and support if the patient's anxiety should pose a problem while the family was away.

The patient experienced minor tension during the flight to Europe but found that after landing his anxiety rapidly diminished and that the five weeks of his vacation were among the most relaxed and enjoyable he had spent for many years. The flight home was relaxed, and he experienced no tension. Toward the end of the vacation one of his children developed a gastrointestinal upset with a high fever and chills, but the patient handled the situation calmly and made appropriate arrangements.

When seen on his return the patient reported his pride at accomplishing this feat and his feeling that the whole exercise had served to rekindle his self-confidence. During this interview I chose to emphasize the need for a reassessment of the patient's life-style. He was encouraged to plan more breaks in his business routine and to get away with his wife and family. He was able to discuss with understanding his preoccupation with vocational performance and relate it to his long years of vigorous training. He established some definite goals to discuss with his wife in terms of mutual recreational plans.

When the patient was seen again six weeks later these plans were reviewed and definite progress was noted. He was planning to attend a professional convention in two weeks. The thought of this trip was producing minor anxiety, but he anticipated no difficulty in managing it. A phone call on his return confirmed that the experience had been successful. A 12-month follow-up visit revealed that he had successfully pursued his intent of establishing a more balanced life-style. He had made several other trips alone and with his wife and was attending more concerts, plays, etc., than he had for many years. He was relaxed and felt more at ease with himself and was satisfied with his progress.

DISCUSSION

The management of this patient involved a variety of therapeutic modalities. The basic initial treatment approach was that of reciprocal inhibition and desensitization, as described by Wolpe (1). This was applied in an extremely concentrated and intense fashion. The entire hierarchy of nine items was covered in a single prolonged interview with virtually no pause between progressions. Satisfactory relaxation was achieved through the use of a small dose of a minor tranquilizer, relaxation exercises, and the induction of a light hypnotic trance. Posthypnotic suggestion was also used.

Rather than allowing a random application of the material covered during reciprocal inhibition, a specific task was assigned immediately following the therapy session. Thus therapeutic use was made of the impetus built up during the long initial session. By making a plane flight without significant anxiety, the patient demonstrated to himself in dramatic fashion that he was able to break through his phobia of flying. This single session together with its assignment virtually eliminated the phobia component to the presenting symptoms. Subsequently, the patient expressed little anxiety concerning airplanes or flying per se. A rapid removal of this component allowed the future sessions to deal with the patient's more general concern about being away from home, away from medical resources, and unable to deal with crises.

The intensive application of reciprocal inhibition and desensitization has some correlation to implosion therapy as initially described by Stampfl and Levis (2, 3). This technique has been clinically applied by a number of workers, notably Hogan, Kirchner, Levis and Carrera, and Hodgson and Rachman (4–10). The technique attempts to create intense anxiety in the office situation through the process of imagining the feared object or situation. The subject is encouraged to repeatedly immerse himself in the threatening scene and to experience the extent of the physiologic anxiety equivalents. By performing this repeatedly, the intensity of the reaction gradually subsides. Stampfl and Levis explain that "the emphasis is not upon the acceptance of interpretations, but rather upon the extinction of anxiety-evoking conditioned stimuli (cues) which provide both motivational and reinforcing properties for perpetuating the patient's symptoms (avoidance responses)" (3). The clinical reports in the literature, however, are far from convincing. Many deal with presumably well-functioning students with a specific phobia of snakes or rats. The application

of these findings to clinical cases is problematic. Other studies rely exclusively upon inadequate measures of improvement, such as shifts in scales in the Minnesota Multiphasic Personality Inventory.

On a theoretical basis, there is a fundamental difference between implosion therapy and reciprocal inhibition. The former argues that if intense emotional reactions occur in the absence of primary reinforcement, extinction of neurotic behavior patterns that were learned and perpetuated by anxiety will occur. The latter therapy is based on the concept that two opposing states, anxiety and relaxation, cannot coexist. The two therapies begin, as it were, at opposite ends of the stimulus hierarchy.

However, the methods used in the treatment of this patient have from a practical, if not a theoretical, standpoint considerable similarity to implosion therapy—namely, the prolonged immersion of the patient in feared fantasies. There is some similarity to the negative practice technique in which the subject is instructed to practice the target response deliberately and repeatedly (i.e., tics). It is theorized that stable relationships between stimulus and response are interrupted because the response is being deliberately emitted under all sorts of stimulus conditions. More recently, Suinn and Hall have reported on short-term intensive desensitization procedures with both individuals and groups (11, 12). Implosion therapy, negative practice, and the intense application of reciprocal inhibition all use massed practice.

The general principles of supportive psychotherapy were heavily utilized during the initial therapy period of this patient. These involved the use of moderate doses of a minor tranquilizer, my verbally expressed expectations for the outcome of treatment, and my reassurance and availability (for example, when the patient's phobia was specifically challenged during his commuter plane flight). The use of a relaxation tape allows the patient immediate access to the therapist's voice in times of stress and thus provides emotional support in addition to the physiologic effects of relaxation. Dependence on the therapist was encouraged as a time-limited device to assist in the resolution of the crisis situation. By my insistence that the feared activity be actually consummated in a real-life situation, however, the patient was able to prove to himself that he could master his fears and thus could demonstrate his independence from the therapist. This interpretation was encouraged.

It is important to acknowledge the role of supportive psychotherapy during the application of behavioral modification techniques. Treatment results may be seriously altered by the presence or absence of a purposely cultivated positive therapeutic relationship.

At the time of first contact the patient was in a state of emotional decompensation characterized by anxiety, a sense of futility, and a diminished sense of self-esteem. He demonstrated considerable dependence on me, including unrealistic expectations of my power and abilities. However, in the two sessions following the patient's return from Europe, short-term psychotherapeutic principles were used, and his dependence was specifically curtailed.

Throughout his adult life this patient had functioned adequately in vocational, social, and family areas. This was his first episode of significant emotional decompensation. Rather than encouraging a reconstruction of childhood experiences and early family relationships, I chose to interpret to the patient his pattern of excessive devotion to work and his difficulty in accommodating personal needs for recreation and family activity. This was presented as a common difficulty for professional people. The patient readily acknowledged this pattern.

He was encouraged to use his effective organizational skills in the specific task of planning alterations in his life-style. His recent successful vacation plus a strongly positive transference relationship ensured motivation for this task. By translating personality conflicts into specific behavioral goals, they are rendered more concrete. Focusing on a specific issue is frequently necessary in the context of short-term psychotherapy, in the expectation that more widespread changes will occur following an initial shift. During the posttrip period the patient used me as a resource as he focused on the issues of his compulsive work-oriented life-style, and he has attempted to alter it. The encouragement of time-limited dependency is a useful (perhaps inevitable) tool in crisis situations. As this patient's symptoms subsided, the issue of dependency and its resolution was clearly discussed. There is evidence to suggest that the brief therapeutic content in this case (eight sessions) proved useful not only in dealing with a specific phobic crisis but also in promoting a reevaluation of life-style and the inauguration of effective changes.

The treatment of this patient demonstrates a natural sequence of therapeutic approaches. The presenting complaint of phobia of flying was handled through the intensive application of reciprocal inhibition. As this was resolved, more general concerns of availability of medical care and general self-confidence emerged. These were handled through relaxation exercises and supportive psychotherapy. These measures allowed the successful completion of the feared trip and laid the stage for the application of short-term psychotherapeutic measures. The latter were applied to a representative area of conflict and were objectified into behavioral goals. By dealing with specific symptoms initially, it was possible to eventually arrive at much more basic problems of life-style. An evolving therapeutic approach such as this is only possible if the therapist is familiar and comfortable with the application of a variety of therapeutic modalities. The treatment decision becomes not the choice of a technique for the patient, but rather the variety of techniques and the sequencing of their application.

DISCUSSION

EUGENE M. CAFFEY, JR., M.D. (Bowie, Md.)—Dr. MacKenzie has presented a case report dealing with a most contemporary, and perhaps growing, problem: the fears aroused by traveling in airplanes. It has been said that such reports are the foundation of medical writing (1). As in this instance, the story of a patient-physician effort may also serve as a foundation for discussion of related matters. Dr. MacKenzie has incorporated a plea for eclecticism in therapy—to use whatever is necessary to help the patient (an ancient medical rule)—and some comments on behavioral modification approaches.

There is increasing awareness among those who study anxieties about flying and frank refusals to use air transportation that the deep interpretations of the meaning of flying often miss the mundane coincidence that sets the posture of apprehension. In this timorous traveler, who might have quite reasonably been avoiding a European excursion with a sizable family, we find the basic personality, described by Aronson, of those who fear flying: "Ambitious, hard-driving, successful people . . . are particularly likely to become anxious if they do not have things under control. These individuals abhor the passive role of the airline passenger" (2). Whatever these personality traits may betray of neuroticism, a key experience of this patient was of possible suffocation while far from help. The illustration fits well the statement of Rachman that:

> Human phobias are learned responses. They can be acquired by exposure to a single intensely painful or frightening situation, but are more probably acquired as a result of repeated exposures to sub-traumatic situations .... Like other neurotic reactions, phobias can be regarded as persistent, unadaptive reactions which are strongly colored by the subjective, autonomic and motor manifestations associated with anxiety (3).

What did Dr. MacKenzie do to help this handicapped mar who was so effective in most of his personal and public life? H crossed some boundaries and compounded a remedy from sev eral schools of therapy: psychotherapy (psychodynamic an supportive), behavior therapy (reciprocal inhibition and hierar chical desensitization), hypnosis, and pharmacotherapy, in a overall short-term treatment including, commendably, the ofte overlooked period of follow-up and opening up of more com fortable directions of living after the main symptom ha abated.

A major component of the treatment was that of desensi tization. As presented, the extended initial interview is an ex ample of a well-executed, classic Wolpe desensitization. It con tained little that was suggestive of the practice of implosiv therapy, however. I do not recall the author describing th heightening of the patient's anxiety and tension and fear by th efforts of the therapist, so vividly set forth by Hogan and Kirch ner (4). In keeping with Stampfl and Levis (5), I feel that th procedures used here and those of implosive therapies are both behavior therapies since they similarly rely on the learning an conditioning models of symptom origin and modification.

Regardless of the refinements of classification, it is inter esting to hear of the successful treatment of a sufferer of aviato phobia—a word that exists but is hard to find, unlike the situ ation it describes.

A Study of Prediction and Outcome in a Mental Health Crisis Clinic

BY LOUIS A. GOTTSCHALK, M.D., RUTH A. FOX, M.D., AND DANIEL E. BATES

Sixty-eight patients who came voluntarily to a crisis intervention clinic were randomly assigned to one of two groups. Those in the first group received immediate intervention therapy while those in the second were put on a waiting list. By the end of six weeks (and after minor changes in the makeup of the groups were taken into account) there was no significant difference in the psychiatric morbidity scores of the two groups; both had improved. The authors used a variety of pretreatment and posttreatment measures and found that the best predictor of a patient's condition at the end of six weeks was his pretreatment psychiatric morbidity score. The authors conclude that individuals vary in both their reactions to life crises and their therapeutic needs and that the central issue may not be the recovery itself, but the difficulty and pain with which it is achieved.

WE UNDERTOOK THIS STUDY of patients who seek treatment at a mental health crisis clinic for several reasons: 1) to determine whether patients who receive brief crisis-oriented psychotherapy, with or without concomitant psychoactive drug therapy, show greater improvement in functioning than patients who are kept on a waiting list without immediate treatment; 2) to identify pretreatment variables that might serve as predictors of which patients will profit most from clinic treatment; and 3) to attempt to replicate the findings of a similar research study that had been undertaken previously in Cincinnati, Ohio (1).

METHOD

The subjects were patients who came voluntarily to the Mental Health Crisis Intervention Clinic, Orange County Medical Center, because of some life situation or emotional experience with which they had serious difficulty in coping.

To minimize observer bias, all patients were screened, evaluated on pretreatment, and posttreatment variables were evaluated by a member of the research team rather than by the treatment team. The following measures were used:

Content analysis scores derived from five-minute speech samples. At the beginning of a tape-recorded interview, the patients were asked to talk for five minutes about any interesting or dramatic life experiences they had ever had. From the typescripts of these speech samples, various psychological scores (Social Alienation-Personal Disorganization, Human Relations, Hope) were obtained by means of the Gottschalk-Gleser content analysis method, a measurement procedure for which satisfactory reliability and validity have been established (2). The Social Alienation-Personal Disorganization Scale is especially designed to distinguish schizoid trends and the schizophrenic syndrome, but it also functions effectively as a discriminator of general psychiatric morbidity (2). The Human Relations Scale measures the patient's current and typical desire for gratifying, supportive, and constructive human relationships (3). The Hope Scale measures the degree of optimism, sense of purpose in existence, and the positive outlook expressed by the subject (4). All five-minute speech samples were scored independently by content analysis technicians who had been trained to code speech according to the Gottschalk-Gleser method with high reliability and who were completely blind to the identity of the patients and the purpose of the study.

Psychiatric Morbidity Scale (PMS). A standardized psychiatric interview was tape-recorded. The interview was designed to elicit the current psychiatric symptoms and to establish the degree to which these psychiatric problems had disturbed the patient's typical functioning level. The patients were asked to talk about the problems that led to their coming to the clinic. They were specifically asked about current psychological symptoms, such as anxieties, depression, and fears; current behavioral signs, such as excessive drinking, not fulfilling family responsibilities, or crying; current interpersonal problems, such as withdrawal from or expression of anger toward people; and current somatic symptoms, such as cardiac palpitation, insomnia, or weakness. On the basis of a patient's responses, a psychiatric morbidity score was obtained by a method that has been described and tested elsewhere (1).

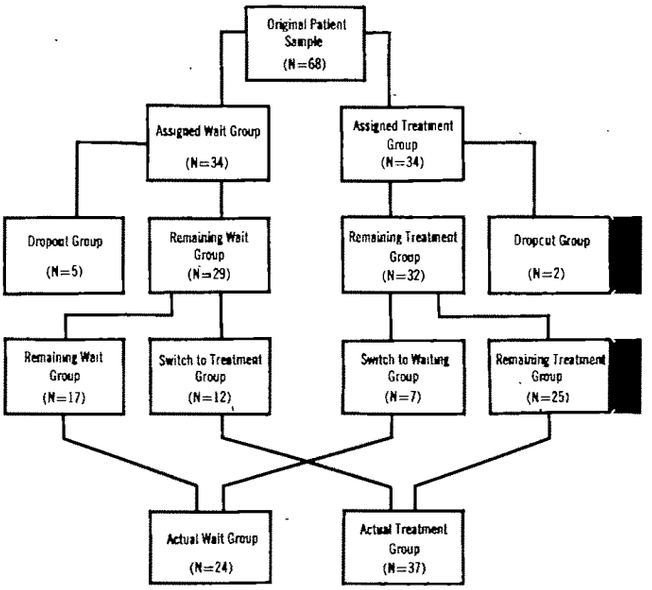
Approximately six weeks after the initial interview, we obtained another five-minute speech sample and a follow-up tape-recorded, standardized interview that were identical in format to the initial measures. The same interviewer took both sets of measures. The format of the interview and the PMS have been published recently in slightly modified form (5).

The authors are with the Department of Psychiatry and Human Behavior, College of Medicine, University of California at Irvine, Irvine, Calif. 92664, where Dr. Gottschalk is Professor and Chairman, Dr. Fox is Clinical Instructor, and Mr. Bates is Research Associate. Dr. Gottschalk is also Director, Psychiatric Services, Orange County Medical Center, Orange, Calif.

The authors wish to thank Gunnar Mazaroups, M.D., for his technical assistance and Herman Birch, Ph.D., for his statistical assistance.

The initial scoring of the interviews was done by the research interviewer. They were then rescored by a research associate who listened to the recordings but had no information on whether the patient had received immediate crisis intervention psychotherapy or had been asked to wait. The interrater reliability on the PMS for 92 interviews was 0.73 ($p<.001$), a level that indicates there was no observer bias. This high level of reliability and lack of observer bias indicates that this study approximated a single-blind design.

Ego strength and weakness scores. Paper and pencil tests and questionnaires were also administered to the patients when they came to the clinic. These included the Jacobs Ego Strength and Ego Weakness Scales (6), Barron Ego Strength Scale (7), and the Anant Belongingness Scale (8).



Embedded Figures Test scores. The relatively small number of patients who could cooperate were administered the Embedded Figures Test (9), a measure of field dependence-independence.

A patient who impressed the research interviewer as probably requiring immediate psychiatric hospitalization or as having serious medical problems was not accepted for this study. Only about eight percent of all patients coming to the crisis clinic fell into this category. The remaining patients were randomly assigned to either a therapy group (Assigned Treatment Group) or to a waiting-list group (Assigned Wait Group). Patients in the Assigned Wait Group were told that there were no immediate opportunities for them to receive psychiatric assistance, but that their names would be placed on a waiting list, which meant they would have to wait about six weeks to begin their treatment. Those who were in the Assigned Treatment Group received brief crisis psychotherapy within one hour of the initial evaluation and subsequently received from one to six treatment sessions from a psychiatrist, clinical psychologist, psychiatric social worker, or mental health associate. At the discretion of the psychiatrist who was consulted on the treatment plans for all patients, psychoactive medication was also prescribed for some patients. The crisis psychotherapy that was given to the patients was patterned after the crisis intervention treatment described by others (10–12).

RESULTS

On careful inquiry at the time of the follow-up interviews, we learned that a sizable number of patients initially assigned to the treatment group or to the waiting group (put on a waiting list) switched groups, that is, some of those who were in the treatment group did not appear for treatment and some of those who were in the waiting group obtained treatment elsewhere. The occurrence of these shifts from group to group and the number of dropouts (patients who failed to reappear at the clinic and could not be contacted in spite of strenuous efforts to do so) were recorded. The changes in the initial random assignments of the patients to a treatment or waiting list group are illustrated in figure 1.

FIGURE 1
Changes in Initial Assignments of Patients

Demographic Data

The average age of the entire sample of 68 patients was 32.01 years (standard deviation [S.D.] = 10.07); the average educational level was 11.54 grades (S.D. = 2.31). Eleven of the 68 patients were Mexican-Americans and the remainder were Caucasians. In the Hollingshead-Redlich two-factor classification system, none of the patients was in class I, three were in class II, 14 were in class III, 24 in IV, 16 in V, and 11 were not classified.

The Cincinnati sample (1) had a social class distribution that was very similar to that of our southern California sample, but the racial composition was different. Thirty-eight percent of the patients in the Cincinnati sample were black, while 16 percent of our California sample were Mexican-Americans.

Pretreatment Measures

After eliminating the dropouts, the Assigned Treatment Group and Assigned Wait Group were compared on the pretreatment measures using Student's t test. The differences in these scores were not significant.

All patients had been asked in the interview about their use of psychoactive drugs. After eliminating the dropouts, we compared the pretreatment scores of patients who had taken psychoactive drugs before treatment with those of patients who had not. The average Barron Ego Strength Scale scores were significantly lower ($t=2.16$, $p<.05$) for those who had been using psychoactive medications before treatment (16.90) than for those who had not (19.43). PMS scores and Embedded Figures scores tended to be higher and Hope scores to be lower for the patients who had been using psychoactive medications, but these differences were not significant.

Posttreatment Scores

The 37 patients in the Actual Treatment Group had an average of 2.7 treatment sessions (S.D. = 1.6), which ranged in duration from 20 to 50 minutes. We cannot assume that there is an absolute uniformity in the treatment over successive sessions because we are dealing with different therapists with varying skills spending varying periods of time with different patients. The Actual Treatment Group patients, however, definitely received more "treatment" than the patients in the Actual Wait Group, who received only the tape-recorded interviews.

An analysis of covariance[1] was performed on the posttreatment PMS scores, which were individually adjusted with reference to the pretreatment levels. Using a 2 × 2 × 2 × 2 factorial design, the patients were categorized by their actual conditions of treatment (Actual Treatment Group versus Actual Wait Group and psychoactive medication during treatment period versus no psychoactive medication during treatment period), by the experimental conditions they were assigned to (Assigned Treatment Group versus Assigned Wait Group), and by pretreatment drug use (users versus nonusers). We hoped that these last two categorizations would allow us to isolate subpopulations of the total experimental group and perhaps control for the self-selection into treatment conditions by the patients who switched groups. However, no significant differences or interactions were found.

A similar analysis of covariance was performed in which posttreatment Social Alienation-Personal Disorganization Scales were individually adjusted with reference to pretreatment levels. No significant differences or interactions were found.

Prediction of Outcome

On the basis of the correlations among various measures, a prediction equation for posttreatment Psychiatric Morbidity Scale scores (PMS_2) was obtained. The predictive pretreatment measures were the PMS scores (PMS_1), Social Alienation-Personal Disorganization Scale scores ($SAPD_1$), and Human Relations Scale scores (HRS_1). For the Actual Treatment Group (N = 33),[2] a multiple correlation of +0.62 was obtained; the prediction equation was $Z(PMS_2) = 0.506\ Z(PMS_1) - 0.237\ Z(HRS_1) - 0.007\ Z(SAPD_1)$. For the Actual Wait Group (N = 22), R = +0.57 and the prediction equation was $Z(PMS_2) = 0.408\ Z(PMS_1) + 0.049\ Z(HRS_1) + 0.340\ Z(SAPD_1)$.

These were the same variables that were found to have predictive value in an earlier and somewhat similar study conducted in Cincinnati (1). In that study too, the major predictive variable, the one that accounted for most of the multiple correlation, was the pretreatment Psychiatric Morbidity Scale (PMS_1). This meant that the more disturbed the patient was initially, the less favorable his outcome was six weeks or more later. The greater his initial interest in and motivation for satisfying human relationships (HRS_1) and the less his Social Alienation and Personal Disorganization ($SAPD_1$), the better the outcome six weeks later. (In the present study, however, these last two predictors were weaker than in the Cincinnati study.) In the Cincinnati study, the multiple correlation was +0.54 and the prediction equation was $Z(PMS_2) = 0.380\ Z(PMS_1) - 0.580\ Z(HRS_1) - 0.164\ Z(SAPD_1)$.

Simple inspection of the beta weights will show that there were some differences in the prediction formulas for the Actual Treatment and Actual Wait Groups that suggest that certain people are more likely to improve with crisis treatment than without it, although the average amount of improvement in the two groups showed no difference.

TABLE 1

Partial Correlations of Pretreatment Measures with Posttreatment Psychiatric Morbidity Scores (PMS_2)

Pretreatment Scores	Posttreatment Morbidity Scores (PMS_2)			
	Actual Treatment Group		Actual Wait Group	
	Correlation	N	Correlation	N
Social Alienation-Personal Disorganization	+0.16	35	+0.32	23
Human Relations	−0.26	35	−0.18	22
Hope	−0.03	35	+0.17	23
Jacobs Ego Strength	−0.10	32	−0.27	23
Jacobs Ego Weakness	+0.06	32	−0.08	23
Barron Ego Strength	+0.11	33	+0.02	24
PMS_1	+0.58	37	+0.46	24
Embedded Figures Test	+0.53	17	+0.18	17

Intercorrelations

Table 1 gives the partial correlations between the posttreatment PMS scores and eight pretreatment measures. The PMS_2 scores are corrected for correlation with the PMS_1 scores. The correlations for the Actual Treatment Group and Actual Wait Group tended to be in a similar range on all measures except the Embedded Figures Test (EFT_1). Table 1 shows that pretreatment Hope scores correlated significantly ($p < .05$) with greater change (improvement) in the Social Alienation-Personal Disorganization scores only for those patients in the Actual Treatment Group, and these same Hope scores correlated significantly ($p < .01$) with less change in Human Relations scores only for those patients in the Actual Wait Group. Also, the Embedded Figures Test scores correlated significantly ($p < .05$) with increases in Human Relations scores for the Actual Wait Group ($r = +.62$) but not for the Actual Treatment Group ($r = -.14$) among those patients for whom we were able to obtain Embedded Figures Test scores (table 2).

These findings again suggest that certain types of people may be more inclined to improve when receiving

[1] The analysis followed the general linear hypothesis model, using the BMDS64 program of Dixon (13) specifically.

[2] The multiple R could only be calculated for patients without missing scores.

TABLE 2
Correlations Between Pretreatment Scores and Difference Scores (Measures of Improvement)

Correlations*	Actual Treatment Group			Actual Wait Group		
	Correlation	N	Significance	Correlation	N	Significance
EFT_1 and (HRS_2–HRS_1)	–0.14	16	n.s.	+0.62	15	$p<.05$
Barron Ego $Strength_1$ and (PMS_2–PMS_1)	+0.37	33	n.s.	+0.24	23	n.s.
Jacobs Ego $Weakness_1$ and (PMS_2–PMS_1)	–0.28	32	n.s.	–0.13	22	n.s.
$Hope_1$ and ($SAPD_2$–$SAPD_1$)	+0.42	34	$p<.05$	+0.31	23	n.s.
PMS_1 and (PMS_2–PMS_1)	–0.65	37	$p<.01$	–0.55	23	$p<.01$
$Hope_1$ and (HRS_2–HRS_1)	–0.33	33	n.s.	–0.66	22	$p<.01$

brief contact crisis treatment, while others, who are obliged to wait four to six weeks for such treatment, undergo some improvement with only the prospect of receiving treatment in the near future. On the other hand, in both groups, the sicker patients are likely ($p<.01$) to have less improvement, as indicated by the significant negative correlations ($r=-.65$ and $r=-.55$) between the pretreatment PMS scores (PMS_1) and the change occurring in such scores (PMS_2–PMS_1). These observed differences in the presumptive predictors of outcome in the Actual Treatment and Actual Wait Groups should, of course, be replicated in further studies.

DISCUSSION

Other investigators comparing treatment outcome in a treatment group versus a waiting list group have not mentioned switches of patients from one assigned group to another. The switches of patients from one of our originally randomly assigned groups to another makes us wonder whether our experience is unique or whether other investigators have simply failed to note and document such occurrences. This phenomenon, we suspect, is commonplace and poses an obstacle to securing randomly selected groups, a procedure that is necessary for making meaningful statistical comparisons between groups.

After seven patients dropped out, our remaining Assigned Wait Group patients manifested somewhat more psychiatric disability than our Assigned Treatment Group. Then, after some patients switched from one group to another, the Actual Treatment Group patients now had more dysfunction than the Actual Wait Group. This change appears to result from the high psychiatric morbidity of patients who switched from the Assigned Wait Group to the Actual Treatment Group.

Use of Pretreatment Psychoactive Medication

The fact that the crisis center patients who took psychoactive medication before treatment initially had significantly lower Barron Ego Strength scores and a stronger tendency to have higher PMS scores than other patients emphasizes that the use of pharmacologic agents, in itself, designates a subgroup of patients who are generally more incapacitated than other patients. That most of the patients taking psychoactive drugs did not receive these drugs by prescription from a physician but from "over-the-counter" sources or from relatives or friends suggests that this relative incapacity is not physician-induced. We cannot be certain whether lower ego strength or higher psychiatric morbidity is brought on by or precedes the use of psychoactive drugs, but we are inclined to believe that it precedes drug use.

We have found that patients who receive an average of 2.7 treatment sessions of 20 to 50 minutes each are improved, but no more improved at the end of six weeks than those who are still waiting for therapy. There are a number of possible explanations for these findings; we suspect that choosing among these alternatives will be influenced by whether one believes in the value of crisis intervention treatment. The alternatives include:

1. If a diagnostic and evaluative interview by a researcher who does not assume the role of a therapist is as effective as specific crisis intervention therapy carried out by a therapist, then it is the nonspecific aspects of the human relationship with a professional in the clinic that accounts for the improvement in the crisis patient's functioning six weeks after coming to the clinic. This conclusion would be a blow to those mental health professionals who assert that training in crisis intervention psychotherapy requires the inculcation of goals, techniques, and attitudes in the therapist. We find the hypothesis that crisis intervention therapy has specific, as well as nonspecific, features attractive, but more evidence is needed to support this view.

2. Crisis intervention may have been available in some form from friends and relatives outside the crisis clinic for the patients who were in the Actual Wait Group. This would account for the considerable improvement of these patients in six weeks.

3. Most patients suffering from life crises recover spontaneously within six weeks regardless of the kind of care they receive (10, 14). Klerman and Cole (15) also as-

erted that 50 to 60 percent of patients with acute depression and acute anxiety reactions recover within two to six weeks without receiving psychoactive drugs or any other form of treatment.

4. The analysis of covariance design, which adjusts for differences in initial (pretreatment) scores, may be statistically elegant but pragmatically inadequate; this procedure may not take into account important initial differences in the relative values of the pretreatment measures for our two groups.

5. The comparative amount of functional improvement in two groups of patients, each receiving different treatment programs, may not be the relevant issue; the central issue may be how much discomfort and suffering these patients had to undergo in the process of recovering from their crises. This issue was not addressed in this study.

Our study, at first glance, suggests the radical view that, with the exception of patients needing hospitalization, crisis intervention clinic patients may not need to be seen for specific crisis treatment since a diagnostic interview that is not focused on therapy may be of equal avail. We think that to hold such a view firmly is premature, but that our study has heuristic value in this connection. More credible is the notion that "naturally" reparative tendencies help people over life crises in a six-week period. Whether recovery is more comfortable and easier with crisis intervention is a different issue and may indeed be the essential difference in the experience of treated and waiting-list patients. We know, for instance, that minor surgery can be equally successful with or without anesthesia and that the healing rate of an infection is not appreciably influenced by an analgesic. But the suffering and pain experienced by patients in these situations is considerably reduced by an anesthetic or analgesic. Hence, this facet of treatment and outcome needs to be examined in evaluating the effectiveness of crisis intervention treatment as well as the comparative degree of functional improvement of the patient six weeks after coming to a crisis clinic.

Usually, crisis intervention aims at improving the coping mechanisms of patients so that they become more resilient in the face of later, similar life crises. Here again, our study did not examine this facet of outcome. We know of no controlled studies that have sought to demonstrate decisively that this important goal of crisis therapy has ever been attained; but we believe, on the basis of impressionistic longitudinal clinical observations, that experienced psychotherapists are capable of achieving such goals.

Prediction of Outcome

The prediction formulas for a favorable outcome for our two groups are similar to the prediction formula obtained in the earlier study with patients of approximately similar socioeconomic background in Cincinnati (1). The differences that exist between the two prediction formulas may be attributable to ethnic-racial differences in the two samples. Small differences in the beta weights of the prediction formula for our Actual Treatment and Actual Wait Groups and the correlation of the Embedded Figures scores with the outcome measures suggest that the people who improve with brief crisis therapy in our crisis center may be different from those who improve while waiting six weeks for such therapy (tables 1 and 2). If so, other investigators (16–18) who claim that there is very little functional difference between treated and waiting patients at the time of follow-up may be missing the differences in the types of people involved. It would appear that some patients have the capacity to respond favorably only with human interactions while others respond to stress with great resilience and respond very little, or even negatively, to specific human therapeutic intervention.

The Therapeutic Utilization of the Juvenile Court

BY YEHUDA NIR, M.D., AND RHODA CUTLER, PH.D.

The authors describe a collaborative program between an adolescent psychiatric clinic and a juvenile court that has resulted in the successful handling of otherwise untreatable court-referred adolescents. The approach used in this program has overcome two major problems in the therapy of adolescents: resistance to treatment and the tendency to act out. Court authority brings an abrupt halt to the chain of events perpetuated by the patients' behavior and at the same time intensifies the current crisis, thus making the patient more available for help.

THE CHANGES in the social and moral atmosphere of our times, the increased use of drugs, and the prominence of an adolescent subculture are being reflected in the number of acting-out delinquent adolescents in our society. Juvenile delinquency seems to increase in direct proportion to the complexity and prosperity of a society (1). The news media report numerous antisocial acts performed daily by young people, often in groups. They come from all social, religious, and economic strata and their number is constantly on the rise. During the period 1960–1970, the 10- to 17-year-old age group had a 25 percent population growth, while arrests in this age group increased by 113 percent. The increase in arrests in the over-18-year-old age group was only 16.9 percent (2).

Despite this significant increase in the incidence of juvenile delinquency, psychiatric treatment facilities remain limited, insufficient, and often ineffective. In an attempt to cope with this rise in delinquency, society resorts more and more to an authoritarian approach and, as a result, the burden of this major social problem falls on our legal system—or more specifically, on the juvenile courts.

This development has placed the juvenile court in a central position in relation to problems of today's "wayward youth." The court has become the emergency room for the psychiatric casualties of our adolescent population. In order to be able to cope with this new role, the courts have had to turn for assistance to the mental health profession, a relatively new development that places new responsibilities on the social workers, psychologists, and psychiatrists employed directly by the court or working with adolescents through other facilities. An exploration of court effectiveness in its new role, the interdisciplinary problems within the court, and the juvenile court's role in mental health are some of the many important issues facing those concerned with the problems of adolescents in our society.

Over the past few decades the juvenile courts have shifted their orientation from the judicial to the welfare approach and have therefore become increasingly interested in the rehabilitation of the adolescent delinquent. Moving away from the concept that punishment is effective either as retribution or as a deterrent has been one of the major factors in this shift.

Dunham (3) ascribed additional influences, such as the social-work orientation of the U.S. Children's Bureau, the broadening jurisdiction of the juvenile court; and prospects of treatment through the increased acceptance of psychoanalysis, which has provided techniques for getting at the roots of delinquency. In addition, there has been a continuing exploration in child development of the concepts of discipline and authority; attitudes have undergone many changes over the years. The Victorian strictness at the turn of the century, which was followed by the overpermissiveness of the twenties and thirties, was based on the false assumption that prevention of all possible frustrations would make the child immune to emotional disturbance. It became clear that permissiveness in and of itself is not therapeutic and that it is of value only within a definite setting. Experimentation with various methods resulted in the development of the concept of friendly understanding but limit-setting authority as the most effective way to deal with children.

Despite the fact that this issue is very important to educators, parents, legislators, and others, insufficient attention has been given to this concept. Outside the psychiatric profession there is still much confusion in the area of authority versus permissiveness, with the juvenile courts leaning heavily toward the latter. This might be a reaction to their past strict punitive approach—possibly a need to make it very obvious that a change is taking place. It is of interest that in two separate papers written in the forties, a judge, P.W. Alexander (4), compared the court to a hospital or clinic where the "sick" patient is diagnosed and treated, while A.C. Nutt (5), a social worker, stated that a juvenile court is primarily a court where legal responsibility is established specifically by law. Whatever the underlying causes, this situation puts

At the time this paper was written, Dr. Nir was Consulting Psychiatrist at the Jewish Board of Guardians, New York, N.Y. He and Dr. Cutler are now at Mt Sinai School of Medicine, where Dr. Nir is Assistant Clinical Professor and Dr. Cutler is Assistant Clinical Professor, and at Beth Israel Medical Center, 10 Nathan D. Perlman Pl., New York, N.Y. 10003, where Dr. Nir is Assistant Chief of Child Psychiatry and Dr. Cutler is Senior Psychologist.

The authors would like to acknowledge the invaluable advice and direction of Dr. Peter Blos in carrying out their work in the clinic.

the mental health practitioner who works with the courts in a paradoxical position. He finds himself recommending probation, placement, or confinement while the court tends to be lenient, to dismiss cases, or to adjust them at intake. Thus we see almost a reversal of roles and a potentially serious conflict that hampers the chances of the client, who is the real concern of both parties.

While many theoretical formulations have been advanced to explain the origin, nature, and prevention of juvenile delinquency, surprisingly little has been written since Aichhorn (6) and Makarenko (7) about specific therapeutic techniques, and insufficient validation of their effectiveness has been reported (8). Among the various alternate approaches reviewed, Empey and Raban (9) applied sociological theory to the treatment of delinquents. They viewed delinquency primarily as a group phenomenon and the task of rehabilitation as one of changing the shared delinquent characteristics. They considered peer-group interaction to be the principal rehabilitative tool and the primary source of help and support. Their program provided a type of social structure that permitted them to examine the role and legitimacy of authorities in the treatment system. Knight (10) reported that older, apparently more interpersonally responsive boys tended to be amenable to confrontative peer-group treatment and to be significantly more successful on parole than other subgroups released from his program.

Behavior modification techniques that utilize operant conditioning have been used to modify the behavior of institutionalized boys (11). However, further empirical study of the duration of these changes in community settings is needed. Alternate strategies have been proposed by others, whose efforts have been directed more toward integrating psychiatric services with probation departments and juvenile court services (12–14). Shoor and Speed (14) maintained that the concept that permissiveness is a sine qua non of mental health is erroneous and stressed that control and firmness may be therapeutic agents in the hands of experienced psychiatrists. They believed that the psychiatrist's role is to support the probation office, to treat cases when psychiatric elements are causative, and to demonstrate a respect for the law and legal processes.

Kaplan and associates (15) pointed out that since the psychotherapy of delinquents has been a disappointing experience in most clinics, probation (the circumstance under which most delinquents are referred) may be regarded as a method of stimulating greater ego control in lieu of the application of external control by incarceration. Compulsory psychotherapy as one condition of probation is therefore encouraged, with the probation officer continuing the same routine as he would without psychotherapy. The hypothesis of Kaplan's group is that the more the acting out by the delinquent can be prevented, the less likely it is for anxiety to be discharged in that way. They believed that the position of the therapist is to oppose the self-destructive impulses of the patient and to nurture ego-syntonic tendencies.

This paper describes the development of a collaborative approach between an adolescent clinic and a juvenile court that has resulted in the successful handling of otherwise untreatable court-referred adolescents. The Court Clinic of the Jewish Board of Guardians in New York City was established many years ago to serve Jewish adolescents who come to the attention of the juvenile court. The clinic's goal has been to offer psychiatric evaluation and treatment to those adolescents and their families whose presence in the court is the result of a psychiatric condition. From the legal point of view the adolescents fall into three categories: 1) juvenile delinquents; 2) persons in need of supervision (PINS); and 3) the subjects of neglect petitions. Their referral to the clinic, which is physically separate from the court, is either voluntary or required by a judge. A volunteer from the Jewish Board of Guardians, who is present daily in the juvenile court, facilitates the referral by describing to the family the nature of the service and its importance to the welfare of the child.

Initially the clinic's procedures were modeled after those of traditional child guidance clinics. Like Holmes (12), we perceived relatively early that very few cases materialized, that the number of broken appointments was very high, and that both the adolescents and their parents were reluctant to accept our services. It became apparent that the usual child guidance approach was ineffective because we were dealing with families in which acting out is an important modality in handling intrapsychic conflict (12, 15, 16).

Because of the complexity of the phenomena underlying acting-out behavior, we found it expedient at an early stage to deal with only one specific aspect of the problem, namely, the family's reluctance to accept our services. It became clear that our young patients were being used by their families to "act out the parent's poorly integrated and forbidden impulses" (17). The parents' resistance to treatment was an attempt to maintain the psychodynamic equilibrium of which the delinquent behavior of the youngster was an integral part, and a recommendation for psychotherapy or institutional placement had little chance of being accepted unless one could find leverages powerful enough to interrupt the tendency toward acting out. In dealing with a similar population at the Thom Clinic in Boston, Von Amerongen (18) found that acting out was for some of these families a family mode of instinct gratification. Describing fathers of those families, she wrote:

> Most of them were able to conform only to minimal and temporary diagnostic demands. Those whose wives and children went on with treatment after completion of the study have stayed away as much as possible. When summoned by us, some have appeared in body, but very few were able to reconsider their attitudes, and others categorically refused to come in, withdrawing increasingly from the family as work with mother and child progressed.

In dealing with the psychopathology of acting-out behavior, it is necessary to understand: 1) whether one is dealing with a real symptom that is the result of an intrapsychic elaboration of a conflict and, if so, where it is anchored within the psychic structure; 2) whether the be-

havior is a result of deficient ego defenses, i.e., breakdown of impulse controls in a psychotic or brain-damaged individual; 3) the role of the immediate and more peripheral environment in the presenting clinical picture; and 4) the intrapsychic and environmental modifications that can be attempted in order to deal effectively with these conditions.

The need to obtain information to clarify these points led us to expand the traditional diagnostic study to a much more extensive assessment. While this is obviously not a new approach to the study of the delinquent adolescent (19), we are stressing it because of the general tendency to deal primarily with the presenting symptoms of the delinquent adolescent rather than to study him in depth. A detailed assessment facilitates the development of an intervention strategy that relies on any one of the intrapsychic or environmental factors mentioned above for its main leverage. Thus we obtained information on the youngster's defensive structure, his stage of development along the continuum of the intrapsychic shifts of adolescence, the significance of his symptoms, and their possible reversibility.

We also gathered detailed information about the youngster's offense and all the events that surrounded it, including the reaction of the community, immediate neighborhood, school, church, etc. The response of the immediate and more distant family, the previous treatment record of the family, the court's prior attitude toward similar cases, the leanings and background of the judge assigned to the case, and the facilities available for carrying out our recommendations were also surveyed. The scope of this assessment has been highly influenced by the fact that we are dealing with adolescents who are in a fluid, rapidly shifting developmental stage, not yet encrusted with set psychopathology (20).

Although it is a demanding procedure, we have consistently attempted to gather this information in a relatively short period since we believe court-referred cases can be handled most effectively at the height of the crisis. A family whose child is apprehended after a delinquent act or who resorts to the use of the court to help control the youngster (a PINS petition) can be considered as being in a state of acute crisis. This is usually the time when tension rises to a climax and the individual and the family not only mobilize their own untapped resources but also tend to solicit help from others.

Since it has been demonstrated that during the emotional disequilibrium created by a crisis one is most susceptible to the influence of others (21), we have attempted to maximally utilize the therapeutic potential of the crisis.

For clarity of presentation, we shall consider the court-referred population as falling into three categories: 1) adolescents for whom court authority is used solely to contain their acting out while they remain in their own milieu; 2) those for whom court authority is used to facilitate placement in a therapeutic institution; 3) those who are intitially unmotivated but are able to become involved in outpatient psychotherapy through the support of court authority.

CASE REPORTS

The following case is characteristic of the first group of adolescents.

Case 1. Barry, 13 years old, illustrates the usefulness of court authority in helping an adolescent to control his surging sexual and aggressive drives. Barry was brought to court because he allegedly performed sodomy on a nine-year-old neighbor. He denied the charges and the court sent him for a psychiatric evaluation. Both he and his parents denied having any problems and saw no need for psychiatric treatment. In our assessment we found an isolated and affectively impoverished boy with paranoid thinking and a fear of being attacked (specifically, knifed). It was felt that Barry's acting out was a result of his uncontrolled aggressive impulses that were expressed sexually—a common pattern in a pubertal boy. He was diagnosed as suffering from a schizophrenic reaction, paranoid type; although psychotherapy and hospitalization were indicated the parents refused to cooperate.

Because of our conviction that Barry was too disturbed not to be in treatment we recommended indefinite probation, subject to periodic reviews, on the assumption that external controls would strengthen Barry's ego defenses and enable him to contain the erupting sexualized aggressive impulses. Although our recommendation was accepted by the court only with reluctance, Barry was placed on probation and remained on it for a year. His behavior during that time was asymptomatic and he was doing well in school. As a result of continuous pressure from the probation department to terminate probation because of his good behavior, and the concern that he would have a court record when he entered high school, we reluctantly conceded.

Four weeks after probation was terminated, Barry was again caught after a new homosexual assault on a nine-year-old boy. This time he was sent to a state hospital for observation.

Due to the particular combination of Barry's pathology and his parents' resistance to treatment, it was necessary to resort to a special strategy. Instead of using the basic therapeutic technique of supporting crumbling ego defenses primarily through the "borrowing of the therapist's ego," we extended this to an interaction between the patient and the law—namely, the court, which could offer him structure, predictability, and specific limits. There appears to be no reason why such interaction cannot take place between the individual and an institution, providing the relationship is a formalized and meaningful one. With patients whose pathology makes them inaccessible for therapy, probation—if precisely planned and implemented—appears to be the approach of choice. It prevents the patient's removal from the community and enables him to pursue his education.

The following case illustrates our approach to the category of adolescents for whom our main goal is placement in a therapeutic environment.

Case 2. John, a 16-year-old, was brought to the court on a PINS petition by his mother because of his uncontrollable behavior and excessive truancy, stealing, and procuring. Two of John's sisters had had psychiatric hospitalizations in the past, and his father had left home suddenly after 21 years of marriage. John had had a long history of maladjustment, and his fa-

ther's leaving had exacerbated his acting out.

Our assessment revealed that although the plan of choice for John would be placement in a residential center, his mother would not accept this because of her close attachment to all her children, especially John. She condoned his behavior as she identified with his acting out and his frequent sexually perverse behavior. Thus the mother gratified her own infantile polymorph-perverse impulses and acted out her own unconscious fantasies. We used two leverages in order to implement our recommendation: 1) we requested the court to keep the case open in order to maintain the crisis momentum; 2) we worked with the attendance officer of the school in order to effect a truancy charge against John, which would make it almost mandatory for the judge to remand the child to a residential treatment center.

The above two cases indicate that although intrapsychic pathology may be responsible for the observable symptoms, the environmental pathology that is an important factor must be taken into account. The implementation of this approach, however, necessitates the development of a truly interdisciplinary orientation. We believe that in such cases the initial intervention (and frequently the only one) has to take place in the sphere of the immediate social environment through the use of community resources and established institutional structures. These cases, which involve a large number of all court-referred adolescents, are the most difficult to handle within the traditional framework because of poor motivation and resistance to treatment. "Treatment," if indicated, can become the responsibility of any team member: teacher, policeman, volunteer, or clergyman. We wish to stress that while we use the term "environmental manipulation" this does not imply an inferior treatment modality but one of choice, based on careful understanding of the patient's dynamics (9).

The third category of cases involves those who are initially unmotivated for treatment and for whom court authority is used differently.

Case 3. David, a 16-year-old, had been brought to the family court on three occasions since he was 11. His first offense was setting fire to a friend; the second, two years later, was assisting in a robbery; and the third was assault while he was intoxicated with alcohol. On each occasion it was recommended that he receive psychiatric treatment. However, the contacts with psychiatric clinics were terminated by his mother shortly after they were initiated. David was the younger of two sons; his father had died when he was six years old. Our assessment revealed that his mother was schizophrenic and that the boy manifested many borderline features as well as a symbiotic relationship with his mother. She perceived any outside contacts with David as threats to their relationship; this caused her to terminate David's prior treatment in the clinic. To prevent the occurrence of this, we made the following recommendation to the court at the end of our assessment procedures.[1]

> In view of the mother's repeated refusal to participate in any treatment program, and in view of David's strong symbiotic tie to her, it would have been extremely difficult at this point to separate the two and to place David. In addition, there are no facilities available for a boy his age except a State Training School or a State Hospital. We would like then to attempt to treat David on an outpatient basis. This will be possible only under a provision that David be placed on a very strict probation in which participation in therapy will be seen as part of probation requirements, and any violation of this requirement will be considered a violation of probation followed by court action.

After the court's acceptance of this recommendation, David was seen regularly in psychotherapy and he never missed an appointment. Initially, he was passively resistant and waited for his mother to pull him out of treatment. The anticipation of disruption made it difficult for him to become involved with the therapist. Although David initially denied this, his resistance diminished when he was assured that his mother could not stop treatment since the matter was in the hands of the court.

The mother, faced with the unequivocal alternatives of having David placed in a state training school or his receiving psychotherapy, chose the latter. To David, the therapist became an ally who on the one hand helped him to stay at home and on the other facilitated emotional separation from his mother, thus making it possible for him to establish a relationship with someone else for the first time. The therapy then became free from environmental interferences.

DISCUSSION

We have attempted to deal in this paper with two major issues in the treatment of adolescents, particularly the delinquent: 1) resistance to treatment and 2) the tendency to act out. Many attempts have been made to explain the adolescent's resistance to psychotherapy and psychoanalysis. Fraiberg (22) considered the aims of puberty and psychoanalysis hostile to each other since the treatment method is perceived as a threat to the defensive structure of the adolescent ego at a time when it is faced with the task of coping with the onslaught of resurgent instinctual drives. To handle this threat the ego brings forth new defenses, which take the form of resistances, refusal to enter treatment, negativism, silence, or abrupt termination. According to Anna Freud (23), the fact that there is little libido available to cathect the therapist results in failure and frustration for both the patient and therapist. Eissler (24), as well as Aichhorn (6), made a distinction between the initial period of treatment, during which the therapist attempts through the use of parameters to engage adolescents in a relationship, and the treatment proper. Aichhorn referred to this initial period as the development of transference.

In our court clinic we have attempted to use court authority as a parameter in dealing with this initial phase. When we believe the youngster can benefit from psychotherapy but this recommendation meets strong resistance from the patient and his family, we generally refer the case back to the court. We then suggest that the youngster be placed on strict probation and that psychotherapy

[1] We always attempt to make our communications to the court precise and to have them supported by available evidence. This appeals to the legal profession and has resulted in excellent cooperation with the courts.

be considered one of its conditions. Failure of the youngster to attend regular sessions in our clinic is considered a violation of probation, with all of its consequences. We feel that this approach deals with a number of important conflict areas. It shifts the adolescent's conflict with his parents and the outside world to one with the clear-cut, definite authority of the court. This new relationship is free of regressive ties, unresolved conflicts, and unfulfilled expectations. It is the law that one has to obey—powerful but anonymous.

Authority, if it is maintained with consistency over a period of time, has a good chance of being accepted by the youngster and may lead to a positive identification with the therapist. As a result we can anticipate a reinforcement of the defensive structure of the ego and the superego, with enhanced ability to cope with the onslaught of instinctual drives.

Psychotherapy by court order creates a new set of interactions and experiences for both the patient and the therapist. The therapeutic situation is seen as a *force majeur*, a societal expectation that has to be faced, explored, and possibly rejected. This obviously must be skillfully utilized by the therapist. The court order thus establishes a new type of rapprochement between the patient and the therapist. Under these circumstances the therapist can avoid being seen as condemning the youngster's behavior, thereby facilitating the identification process and diminishing resistance to the initial stage of treatment. It also preserves the youngster's self-esteem, as he did not ask for help. It is as if he and the therapist were saying: "The court forces us to meet; what do we do now?" The therapeutic interaction takes place then in a "demilitarized zone" of the adolescent's warfare with society and parental authority. The therapist can then align himself, as Aichhorn (6) suggested, with the narcissistic need of adolescence and can try to work with his patient on how to get out of his "mess."

A major theoretical consideration in our approach is our understanding that court authority is perceived by the adolescent as different from the parental one against which he is rebelling. Holmes (12), Szurek (13), and Blos (25) pointed out that the adolescent's proclivity toward action reflects a need to resist the regressive pull of the mother. In introducing court authority we protect the youngster against this pull while at the same time frustrating his attempts to act out. The anxiety created through the removal of the acting out will then by necessity facilitate the psychotherapeutic process.

The very nature of acting out implies a shift from attempts to master to acts of avoidance and to the use of a preverbal kind of problem solving, namely, fantasy and action. This kind of acting out is also associated with impaired reality testing, which is not necessarily psychotic (25). To be effective, a therapeutic intervention must specifically counteract the function of this symptom, which is denial through action. We believe that the function of acting out is blocked by the new situation created by the introduction of court authority and community agency. It brings to an abrupt stop the chain of events that have been perpetuated by the patient's behavior and at the same time intensifies the current crisis, thus making the patient more available for help. The inescapability of court authority is also important in enhancing the patient's ability to test reality.

One must be aware, however, that acting out is psychologically necessary for these patients. Unless one has a foolproof system to contain it, the adolescent will try to find new ways to act out. The extended assessment is thus of major importance because, in addition to providing a dynamic understanding, it offers clues and means for meaningful intervention. It enables us, so to speak, to pull the right strings at the right time. We believe that the combination of authority and psychotherapy (or even the judicious use of authority alone) as "treatment" is particularly justified with adolescents because it can deal effectively with the tendency to act out and is appropriate to the current developmental stage of the patient.

Women Psychiatrists in the United States

BY MARYONDA SCHER, M.D.

The author presents data about the number and percentage of women in medicine, along with their motivations for entering this profession. She also gives recent data about women in psychiatry: their number, areas of specialization, work settings, hours worked a week, etc. After presenting views of the stereotype of the woman physician-psychiatrist and pointing out some of the myths that have been perpetuated, she concludes with the observation that only by working together in the spirit of mutually respectful inquiry can men and women correct the mythologic errors and enlighten one another.

THE POTENTIAL PSYCHIATRIST must be endowed with rich supplies of energy, motivation, perseverance, intellect, and opportunity. He or she must scale a long, arduous, and expensive educational ladder. Nearly a quarter of a century of education—including primary and secondary schooling, college, medical school, internship, and residency—is necessary to earn the title of psychiatrist. Women are endowed with as many of the necessary attributes, including energy, perseverance, and intellect, as men. Yet at every step up the educational ladder, the ratio of women to men decreases. The statistics that bear this out are striking.

Let us examine some of them. In 1967 (1), 2,679,000 young people graduated from high school. That year, as in preceding years, the girls slightly outnumbered the boys (51 percent of the graduating class were girls). That year, 62 percent (1,652,000) of the new high school graduates enrolled in college. Only 43 percent of the enrollees were women. Why the discrepancy? Why should the ratio of women to men drop by eight and a half percent between high school and college? Various authorities (2, 3) estimate that between 75 and 98 percent of the well-qualified students who do not go on to college are women. These are the very students who might be capable of becoming physicians and psychiatrists. Yet these are the ones who are lost from the potential pool of applicants.

What happens to these women that makes them drop by the educational wayside? Two studies offer some answers. The first, a 1960 study of bright children who showed academic underachievement (4), noted that the boys who underachieved differed from the girls in the age of onset. Bright boys who underachieved did so from an early age. In contrast, the girls began to underachieve in high school at about the onset of puberty. These authors concluded that "this contrast is further indication that the achievement drop-off among the girls as they reach maturity is linked to the adult female sex role." The second series of studies (5), carried out in 1969, found that a high percentage of women showed evidence of success avoidance. Young college men did significantly better in competitive tests than their women counterparts. In contrast, the women were able to outperform the men in noncompetitive situations. Many of the women stated that they were actively avoiding success, which they considered to be an unfeminine attribute.

Despite the apprehension of some of them concerning success, women made up 40 percent of the 1967 college graduates. The proportion of women dropped only slightly (three percent) between enrollment and graduation. This suggests that despite negative pressures, women, once started, are almost as likely to finish college as men. But they are not likely to go on to graduate school. Only a small percentage of women apply to graduate programs. Of these, the same proportion are accepted into graduate programs and are provided with support in the form of scholarships and assistantships as men (6, 7). This seems to indicate that women encounter no discrimination in their acceptance into graduate programs. No studies are available, however, on the comparative qualifications such as the grade-point average and aptitude test scores of the men and women accepted.

Revised version of a paper presented at the meeting of the Group Without a Name, Seattle, Wash., September 8–10, 1972.

Dr. Scher is Staff Psychiatrist, Veterans Administration Hospital, 4435 Beacon Ave. South, Seattle, Wash. 98108, and Clinical Associate Professor, Department of Psychiatry, University of Washington, Seattle.

The author wishes to thank Mr. A.H. Kumbar of the APA Division of Manpower Research and Development for supplying data from the 1970 census of psychiatrists.

These data would give a truer picture of possible discriminatory admission practices.

MOTIVATIONS FOR ENTERING MEDICINE

What motivates the few women who do apply to and enter graduate programs? In 1972 Lillian Cartwright published a study of the "Conscious Factors Entering Into Decisions of Women to Study Medicine" (8). She asked 58 women medical students in the 1964 to 1967 entering classes: "Why did you go to medical school?" Their answers indicated multiple and complex reasons, which she was able to categorize under the following headings:

	Percentages
1. Encouragement from others	57
2. Interest (in science, biology, etc.)	48
3. Individuation and self-development	43
4. Mission (altruism, humanitarianism, idealism, etc.)	34
5. Unfavorable evaluation of alternatives	34
6. Response to adversity	22
7. Effects of tradition (parent is physician, scientist, etc.)	21
8. Actualization of parental dream	17

Apparently the encouragement, support, expectations, and hopes (categories 1, 7, 8) of others were important to the majority of women in making their decision to study medicine. At the same time they were exploring their own interests and advancing their self-development.

The comparative attrition rates between men and women in graduate programs are of interest. In medical school women leave their training twice as often as men (16 percent compared with eight percent) (9). Closer scrutiny of these figures reveals that eight percent of the women, compared with three percent of the men, leave school for nonacademic reasons. The remaining women succeed nearly as well as men academically (eight percent versus five percent failures). Whatever the attrition, in 1967 women earned only 35 percent of the master's degrees, 12 percent of the doctoral degrees, and 4.4 percent of the first professional degrees (including M.D., LL.B., D.D., D.V.S., etc.) awarded in the U.S. Women received 574 (seven percent) of the medical degrees that year.

FACTS ABOUT WOMEN PHYSICIANS

I would like next to examine some of the facts about women physicians in the United States. They make up seven percent of all physicians and in 1970 numbered 25,400 (10). Between 84 and 91 percent of these women are professionally active, working either full- or part-time (11). The majority are in pediatrics, psychiatry, general practice, or internal medicine (in descending order). About 70 percent (12, 13) are married, and each family has an average of 2.4 children. The women marry and have their children later than do the men. Nearly all of the women with children have taken leaves from their professional activities during the course of their careers. The percentage of women practicing full-time drops with marriage and with each successive child.

TABLE 1
*Board Certifications Held by Respondents Reporting Any Certification, by Sex**

	Men	Women
Psychiatry	98	95
Neurology	7	5
Child psychiatry/neurology	6	16
Other	4	1

*Fifty-two percent of those replying to the questionnaire answered this question.

On the average, women physicians practice 2,000 hours a year (that is, 40 hours a week, 50 weeks a year). This contrasts with the 2,831 hours a year of the average man physician. The figures include all professional activities such as practice, research, reading, and attending meetings. Women physicians practice 30 percent fewer hours and see one-third fewer patients than men physicians each year. The women take as much postgraduate training as the men, but they are less likely to be certified in their specialty. Forty-eight percent of the women are self-employed and 31 percent are in full-time salaried positions. This contrasts to 75 percent of the men who are self-employed and 15 percent salaried. People in salaried positions are apt to work fewer hours because of their fixed-hour schedules than those who are self-employed. Since a higher percentage of women are found in these positions, this may account in part for the discrepancy between the hours a year worked by men and women.

FACTS ABOUT WOMEN PSYCHIATRISTS

So much for the data on women physicians in general; now let us examine information about those who go into psychiatry. Between ten and 20 percent (12, 14) of the women graduating from medical school in the United States go into psychiatric training each year. In 1970 there were 745 women residents in psychiatry, or 17.7 percent of the total (15). That same year 187, or 16.7 percent of the total, completed their training and 34 (14.1 percent) terminated their training before completion. The statistics show that women complete their psychiatric training as often as men—indeed, U.S.-trained women complete it more often than men. It is of interest that 40 percent of the women psychiatric residents were foreign-born and foreign-trained, compared to 29 percent of the men residents. On the average it takes longer for the woman resident to complete her training than it does for the man.

There are approximately 3,000 trained women psychiatrists in the U.S., making up 12.5 percent of the total.

TABLE 2
*Area of Practice Reported, by Sex**

Area of Practice	Percentage	
	Men	Women
General psychiatry	49	40
Adult psychiatry	13	16
Child and/or adolescent psychiatry	10	22
Psychoanalysis	10	10
Other (including neurology, geriatric, forensic, industrial, etc.)	18	12

*Ninety-three percent of those who reported that they were working answered this question.

Data from two studies are available about these women. In 1964 investigators from the Langley Porter Institute studied 28 of the women who had taken one or more years of training there and compared them with 28 matched men controls (16). They found that 47 percent of the women and 77 percent of the men were Board-certified, a statistically significant difference. Women were less likely to be married: 77 percent compared with 96 percent. The women spent an average of 31.5 hours per week in psychiatric practice, excluding training, reading, and attending meetings; in comparison, men spent an average of 45.7 hours—again a statistically significant difference. The women who were single or divorced worked an average of 37.7 hours per week; those who were married averaged 29.3 hours. These investigators concluded that the mental health manpower needs of the nation would be better met by appointing men residents to those residency programs which tend to be completely filled. They suggested that programs which had unfilled places could tailor their residencies to meet the needs of women. Of course, if this advice were to be followed by residency programs nationwide, women would be doomed to inferior training since the programs that tend to fill are considered superior to the others.

More recent and comprehensive statistics have been compiled by the American Psychiatric Association from the 1970 census of all known psychiatrists in the United States (17). Questionnaires were mailed to 25,755 psychiatrists, of whom 17,383, or 67.5 percent, responded; 1,983, or 11 percent, were women. The median age for both men and women was between 40 and 44 years.

Ninety percent of both men and women psychiatrists reported three or more completed years of training; 34 percent of the women and 50 percent of the men reported certification in one or more areas. Table 1 gives the type of certification held by those reporting any certification; it should be noted that the percentages for the various certifications cannot be added meaningfully since the number of respondents who hold dual certification is not given.

Forty-nine percent of the men reported their area of practice as general psychiatry in contrast to 40 percent of the women. On the other hand, twice as many women (22 percent) were practicing child and/or adolescent psychiatry as men (ten percent) (see table 2).

A higher percentage of women than of men were working part-time, were retired, or were not working; 81 percent of the men and 73 percent of the women were working (table 3).

The women tended to concentrate their work in fewer locations; the men were more likely to diversify their efforts: 62 percent of the men in contrast to 53 percent of the women worked in two or more locations (table 4).

While women work in fewer locations, they still appear in greater proportions than men in state mental hospitals and in educational institutions other than medical schools. They are employed in salaried positions more often than men (table 5).

Women averaged 39 hours of unduplicated work per week and men 49 hours. A discrepancy in the amount of direct patient contact accounted for most of the difference in hours, i.e., women were in direct contact with patients 25 hours each week in contrast to 32 hours for men. Women spent approximately the same amount of time in consultation, teaching, research, and administration as men (table 6).

Both men and women donated an average of eight hours of work each week (47 percent of those working reported). From the questionnaire there was no way to tell whether the donated hours overlapped or were in addition to the other hours reported.

In any case, the average woman psychiatrist's professional workweek had approximately 80 percent of the number of hours of the average man's; she was more likely to be employed in a salaried position; her time was spent in fewer locations and in more specialized areas (especially those dealing with young people); and although she had an equivalent amount of specialty training she was less likely to hold a specialty certificate. From these data, it would appear that women in psychiatry are far more productive professionally than previous studies have shown. Considering the fact that most of them function in the roles of wife and mother in addition to their professional work, they are not only highly productive people but in addition must be efficient and well-organized.

TABLE 3
*Employment Status of Respondents, by Sex**

Employment Status	Percentage	
	Men	Women
Full-time in psychiatry/neurology	78.6	56.0
Part-time in psychiatry/neurology	2.8	16.9
In residency training	14.4	18.9
In other postgraduate training	0.4	0.6
Working in other field	0.7	0.9
Not working, not retired	0.4	1.7
Retired	2.6	5.0

*Ninety-six percent of those replying to the questionnaire answered this question.

*Number of Work Locations Reported, by Sex**

Number of Locations	Percentage	
	Men	Women
One	38	47
Two	30	28
Three or more	32	25

*Ninety-seven percent of those who reported that they were working answered this question.

Other data suggest that they are likely to cost their employers less. We have already noted that, although they had equivalent amounts of specialty training, 34 percent of the women and 50 percent of the men were Board certified. Usually salaries are significantly higher for psychiatrists who are Board certified. For example, a differential is paid by the Veterans Administration on the basis of certification. Since fewer women are certified, more are paid at the lower rate even though they may be as well-qualified as the men. By these criteria women psychiatrists seem to be especially valuable in salaried employment, where they are found in proportionately greater numbers than men.

The literature in medicine and psychiatry focuses on the quantitative manpower needs in these fields. In both, there are alleged shortages. Indeed, if the average man must work between 50 and 60 hours a week, a shortage must exist provided he is working efficiently. In order to rectify this shortage, medical and psychiatric educators attempt to ensure maximum productivity from each of their graduates and graduate a maximum percentage of their trainees. But the question might be asked whether the individual practitioner should be expected to solve this problem. Certainly graduates in other fields are not asked to do so. In physics, mathematics, law, education, and engineering, to name a few, an overabundance of graduates for whom there are few jobs exists. Graduates who do not find employment in these fields are a waste too. But the onus does not fall on the graduate; rather it falls on the schools that produce too many graduates and on the labor market, which cannot absorb the overload. The comparative productivity of women has been studied in fields other than medicine; however, only in medicine does the question arise as to whether their lower productivity should ban women from the field.

SOME VIEWS ON WOMEN IN MEDICINE AND PSYCHIATRY

The emphasis on quantity of productive work underplays the qualitative contributions that women make to medicine in general and psychiatry in particular. In 1964, the president of the Women's Medical College of Pennsylvania, Dr. Glenn Leymaster, detailed some of the attributes that women can bring to medicine (18). He said:

> There are many things men can do in medicine which women can do better; i.e., an interest in the concrete in preference to the abstract problems of the community; a certain innate skill in interpersonal relationships; a sensitivity to the feelings of others; great skill in the use of words; a natural attraction to and for infants and children; an unusual tolerance for detail, even repetitious work; fine manual dexterity.

Daniel Blain wrote (2):

> It is time now to speak of the especial need for women in psychiatry, for perhaps by natural inclination and temperament, women are particularly capable with troubled people. Women make excellent physicians, and they make excellent psychiatrists. They are (usually) better endowed than men with the vital trade tools of human warmth, empathy, and capacity for emotional understanding.

Similarly, May Romm wrote (19):

> Women, through their very uniqueness of being females, mothers, or potential mothers, are natural healers who are endowed with a good deal of patience and who are by nature empathic, intuitive creatures, [and] seem suited to the specialty of psychiatry.

And Dr. Blain (2) quoted Dr. Luther Terry, former surgeon general of the U.S. Public Health Service, as saying:

> Women are good for psychiatry. First, I think that from a biological standpoint, the evidence has indicated that they tend to adapt better to many of the sedentary requirements of psychiatry, particularly of psychotherapy, and that in many respects they have less need of some of the action orientation which is often so important to, and on occasion impairs the effectiveness of, men as psychotherapists. Even more important, I think, from a psychological and sociological standpoint . . . women as a group tend to be more intuitive than men and to function better in a nurturing capacity which is often required in psychotherapy.

The composite stereotype of the woman physician-psychiatrist is awesome indeed. She is portrayed as a

TABLE 5

quiet, patient, healing, nurturant, practical person endowed with "natural" warmth, empathy, intuition, sensitivity, and understanding—a virtual earth mother. Of course, few of these qualities have been scientifically validated as more characteristic of the female than the male of the species, and men and women psychiatrists have never been compared experimentally as to the relative prevalence of these attributes. Nonetheless, the stereotype of the healing mother-physician seems to exist even among respected members of the profession, and perhaps this is a contribution that women could make to medicine and psychiatry. Perhaps women in greater numbers could alter the image that the American public has of the doctor, i.e., the cold, impersonal, scientific man on a gluttonous quest for riches at the expense of his helpless and suffering patients. It would be nice to modify this stereotype too, but women can make far more basic and important contributions than to suffuse the field with femininity.

NEED FOR MUTUAL ENLIGHTENMENT

Women know what it is to be female; they could share their unique understanding of the female experience with other members of the profession. For centuries women have clung to their secrets of female physiology and psychology while men have plaintively proclaimed and amply demonstrated their ignorance of the subject. Men have harbored their secrets, too, although "anatomy is destiny" and anatomical differences have made it harder for them to do so. Out of such mutual secretiveness and ignorance have grown the great sexual myths of history; e.g., that women have fewer sexual needs and are less sexually responsive than men, that men only want "one thing" of women, that the female's psychodynamics are those of the male castrate. The absurd phallocentric theme has dominated the lore of medicine and psychiatry.

Only by working together in the spirit of mutually respectful inquiry can men and women correct the mythologic errors and enlighten one another. But knowledge is power. No one who anticipates exploitation or contempt from another will reveal his or her power-giving secrets. Yet for centuries men and women have exploited one another—have held each other in disdain. In such an atmosphere, mutual enlightenment was impossible. Respect and trust between equals must prevail if we are ever to know each other. That is why more women must become physicians and psychiatrists, that is why the distribution of the sexes in these fields must become more representative of the population they serve; that is why women must not be token members of the medical and psychiatric professions but responsible and respected students of humanity. Then, men and women working together can correct the false and damaging mythology and contribute accurate data to the body of medical knowledge. Then, and only then, will we serve our patients well.

Medicine: A Career Conflict for Women

BY MALKAH T. NOTMAN, M.D., AND CAROL C. NADELSON, M.D.

The authors consider some of the issues involved in women's choice of a medical career. The woman medical student has few acceptable role models available to illustrate the variety of possible life and family patterns. In addition, she must cope with the anxiety of medical school and also define her identity as a woman in a "man's world." Women respond to these challenges in a variety of ways related to individual characterological and defensive styles. The authors recommend several approaches to facilitating the participation of more women in medicine.

THE PERCENTAGE OF WOMEN APPLICANTS to medical schools in the United States has changed little in the past 50 years. This is not true in other countries, where women represent a higher percentage of the total physicians. Of American physicians, 6.7 percent are women, a number lower than in any other Western country except Spain (1). Currently the medical profession loses many gifted potential candidates; it further loses the diversity of talents and the assets that women could bring to it.

Despite some impressions to the contrary, women have generally been admitted to medical school in proportion to their applications (2). Thus if ten percent of the applications received by a school are from women, about ten percent of the students accepted are women. With the low national percentage of women physicians remaining relatively constant, it is important to consider the reasons why many qualified women turn away from medicine.

Many reasons have been given for this phenomenon, including the hypothesis that women are less interested than men in pursuing a medical career (3). To some extent this may be true. However, one must consider the pressures that make the choice of and adaptation to a medical career extremely difficult for women. On the basis of our experience with women in high schools, colleges, medical schools, internships and residencies, as well as with those who have careers in the medical field and our most recent work with a group of women students at Harvard Medical School, we will discuss some of the factors involved in the choice of medicine and in the ability to pursue a medical career. We will also recommend several ways of facilitating the participation of more women in medicine.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with Beth Israel Hospital, 330 Brookline Ave., Boston, Mass. 02215, where Dr. Notman is Psychiatrist and Dr. Nadelson is Associate Psychiatrist. They are also with Harvard Medical School, where Dr. Notman is Assistant Clinical Professor of Psychiatry and Dr. Nadelson is Assistant Professor of Psychiatry.

THE CONSEQUENCES OF EARLY PATTERNS

For most people, the development of personality values as well as the crystallizing of life choices begins early in childhood. Girls in our culture are usually encouraged to choose more passive types of activities because these are considered to be more feminine and more consistent with their later roles. Scientific pursuits in particular are frowned upon and considered to be masculine because of their association with assertiveness, precision, and responsibility. In the process of growing up, girls find that they need to deny aggressive traits even when they are actually functioning in areas where these skills are necessary. There are blatant inconsistencies between the passivity and compliance expected of women in relation to men, and the activity and authoritativeness expected in the role of wife and mother.

A girl who is interested in medicine and who comes from a conventionally structured middle-class family faces potential conflict between her identification with her mother and her interests in a different pattern of life. If her relationship with her mother is close and relatively unconflicted, she may have difficulty because she may see herself as betraying her mother and competing with her to achieve more. If a woman has had a troubled relationship with her mother, she may become uncomfortable in seeking a demanding career because this interest may seem connected with the problems in the relationship as opposed to being a true career interest. A girl's identification with her father's professional role may promise an easier pathway for the development of her own serious career interests, but it may interfere with her relationship with her mother and with the resolution of identity issues. Analogous conflicts may be present for a man, but more external supports are available to him to facilitate the resolution of problems of career choice.

It is difficult to distinguish biological from cultural differences between masculine and feminine roles. However, culturally normative values, particularly for gender differentiation in social functioning, are presented *as if* they were biologically based. Expectations are imposed on boys and girls that may differ from their individual personality structures. The idea that medical training is arduous and inappropriate to combine with family life is introduced early. The problem of combining medical practice with a family is seen as a problem for a woman,

yet we frequently see medical families disrupted by the father's excessive working hours.

Stereotypes may also act in specifically limiting ways for both men and women. The strong, silent type of masculine ideal inhibits the development of sensitivities in men, just as the model of a "proper" woman, helpless and dependent, may inhibit the expression of a woman's activity and independence because she does not want to be considered unfeminine.

Social pressures on a girl who considers a career involving a commitment outside of the home provoke conflicts, particularly when she considers having children. The working mother of young children is often considered an inadequate or "bad" mother; and the woman who chooses not to be a mother is reciprocally viewed as an inadequate woman. Career women whose children develop emotional problems are usually quick to blame themselves for causing the problems. It is interesting that the same criticisms are not made of a woman who spends an equivalent amount of time in volunteer or other charitable activities.

Advisers throughout the years of schooling tend to reinforce the idea that a career in medicine is unsuitable or unrealistic for a woman because of her expected family role as well as because of her "innate" incapacity to meet rigorous demands (as if the demands of raising small children and running a household were not rigorous). The decision for medical school must be made early. Often, by the time a woman has had enough life experience to evaluate the direction in which she would like to go, it is too late to catch up on premedical courses, or she may be told that she is a poor risk because of age, marital status, or children. In other cultures, i.e., western Europe, the same rigorous training is not considered to be too difficult for women.

Applying and gaining admission to medical school seems to be a formidable barrier to many women. A girl asks: "What do I have to be like for them to accept me?" She may look for ways of presenting herself that combine both her own personality and her view of the ideal medical student. She may feel that she must stress those aspects of herself which will gain acceptance. While the same issues confront male applicants, the *idea* of their having a medical career is not questioned.

Admissions committees, in trying to assess applicants, often fall back on the concrete qualities in which men and women seem to differ, such as science grades or aptitude test scores, which have predictive value for performance in the basic sciences in medical school but have no relationship to performance as a physician (4) (see table 1).

A child relies on models of successful people with whom he can identify to help define his role in society. Problems in the development of positive self-image and self-confidence grow out of the reinforcement of the idea that a woman is considered less adequate than a man. Many women enter medicine with these negative feelings about themselves. Those women who have visibly succeeded often represent only a small range of possibilities of life-styles. A girl may see herself as having no choice but to identify with the somewhat vague and scatterbrained conventional feminine style as the only alternative to being termed aggressive and castrating. Such polarization occurs because of the absence of other suitable models for identification for women. (Men are also prone to stereotyping women physicians because of the limited number they encounter.) To cope with the anxiety produced by conflict between the acceptable and desired roles, many women use denial and reaction formation.

In our culture medicine has been viewed as a masculine profession. Expectations in the doctor-patient relationship are connected with this idea. We think of patients as we think of women and children, expecting passivity and compliance from them. Doctors often assume the role of protective father with a dependent child. This model may diminish communication by its rigidity and condescension and thus may prove destructive to the goal of optimal care. Patients contribute to this transference-countertransference phenomenon by viewing the doctor either as a powerful, aggressive figure or as a warm, comforting, supportive one. The patient's early life experiences determine how he or she views the relationship with the doctor. In terms of potential gain to the patient, the possibility of being able to choose a doctor of either sex may be of major importance.

THE WOMAN MEDICAL STUDENT

All students share a variety of stressful experiences when they enter medical school. Since responses to stress are determined by each individual's past developmental encounters and intrapsychic processes, as well as by the challenge of the situation, one would expect to see the use of a variety of types of defense mechanisms to facilitate adaptation. Keniston has described the most frequently found adaptive styles in students as counterphobic, alloplastic, and obsessive-compulsive (5). Students place a special reliance on isolation and intellectualization. The period of medical school coincides with the late adolescent period of identity formation for most students, and the use of "less mature" defenses such as denial may be increased by identification with those physicians who are their teachers. The stresses and responses also change for each student with course material, year in school, and the interpersonal aspects of the student's life.

All students share a common goal—to develop an

identity as a physician. The woman student has an additional task; she must define her identity as a woman in a 'man's world" and cope with the myths about her ability o remain "feminine" and be a doctor. The atmosphere in nedical school is usually highly competitive. A woman :oming from a coeducational school has, for the most part, had the occasion to confront competition with men n her premedical studies. For the student from a woman's college this competitiveness may be a new, frightening, and demoralizing experience.

The conflict between passivity and activity is continually present. Many women students withdraw; they may also hesitate to offer correct answers in order not to appear too competitive. Other women do not seem to feel hampered by these restraints; some deny them, and many others have worked them out previously. Those women who handle the challenge by attempting to be "better men" and to perform as "one of the boys" find themselves able to function well academically, but often, after a few years, they perceive that their social relationships are not as satisfying as they would like them to be. The alternative pseudo-ignorant or flirtatious posture feels false and also contributes to difficulties in handling negative attitudes from other students, faculty, or patients when they do exist and of being an active, decisive participant when this is required.

We have been impressed with the frequent discussion of the hostility that many women students feel is directed at them from peers and instructors; they are reminded that each is taking the place of a man who would be more serious about a career. At the same time, many women do find themselves warmly welcomed.

The woman who attempts to maintain awareness, responsiveness, and objectivity is in a difficult position. She often feels isolated and lonely since she is *not* one of the boys. At times of stress she may receive less support from family or friends than her male classmates do. Most physicians can remember the anxieties aroused by the thought of, and then by the encounter with, the human body—first as a cadaver, then as a patient. All physicians must face life-and-death decisions, and all must learn to cope with the anxiety provoked when the dilemma of how much one must learn in order to avoid *the* potentially fatal mistake is encountered.

The tension of this period and the confrontation with one's human limits include learning to look at suffering, pain, death, and also at sexuality. Anxiety may be denied or displaced in various ways onto other students, instructors, and patients. Women students as a visible minority are not infrequently the targets of displaced anxiety. Men students often seem to have difficulty relating directly to women as colleagues and competitors; instead, they may sexualize their relationships. The women may fall into a pattern of response by reciprocating so that they feel accepted, despite concerns about this mode of interaction. They may feel threatened by it and withdraw from peers and become lonely and at times depressed. Another adaptational pattern is the use of regression. The woman student may find herself becoming dependent on her male laboratory or clinic partner. She may behave in a helpless, childish manner to gain his attention and approval, perhaps in a manner that had successfully accomplished this end in past family experiences.

Another kind of pattern of adaptation derives from the need to appear strong rather than timid. Some women students have a persistent underlying feeling of guilt, as if they have been masquerading as something other than what they are in order to gain admission to medical school. If conflicts lead to ambivalence or hesitation, they are afraid to show it for fear of betraying weakness and of not being "worthy." This is reinforced at times by the attitudes of their doctor-teachers who also handle feelings of helplessness and uncertainty by isolation from their patients and denial of their feelings.

The anxiety and hostility expressed by the jokes at the dissecting table are familiar to anyone who has been a medical student. The few women students are very often the recipients or objects of the jokes. Even though she experiences the same anxiety as the man, the woman student often decides that she must "take it" from her male colleagues so that *women* do not appear weak and inadequate. She learns very early that she is not seen as an individual to be judged on her merit but as a representative of all women who enter medicine.

The nonacademic pressures are great, and perhaps for this reason women do drop out of medical school more frequently than men do (6). Women who leave medical school do so most often in the first year; these students also tend to be the daughters of nonprofessional women (7). The reasons for this may relate both to the identification issues discussed earlier and the conflict about pursuing a career that is not positively valued for a woman, by society as well as by her family. The lack of acknowledgment and support contibutes enormously to the pressure of the experience and the inability to sustain career goals.

Most of the students we have seen have noted that there is a lack of women in prominent faculty and administrative positions to serve as acceptable role models and figures for identification. The need for such figures varies for each student during the course of medical school. Many women medical students, in our experience, seek contact with a group of peers and faculty. Others have individually contacted us at times of stress.

The clinical years often bring a sense of relief despite new issues concerning closeness that arise from direct physical encounters with patients. Many women medical students feel less anxious in the role of caretaker, since it provides a way of combining medical skills with the more traditional expectations of them. It is rare for a patient to be upset because he has a woman student assigned to him. After their initial surprise, many patients even view the situation with relief. This is especially true of those who may look upon a woman as a person with whom they feel less threatened or with whom they can regress or identify, as they feel they can with a mothering figure. Even those men who may initially feel some embarrassment with a woman doctor adapt to this.

As the end of medical school approaches, many women begin to explore how they might define their fu-

ture role as a physician with a family. At this time the married students seem to show increased interest in the life-styles of other women students and faculty. They are seeking additional avenues of identification and other role models. Some women gain acceptance within their student or professional situation only to be regarded as peculiar by the people whom they meet in the world outside of medicine.

During the last two years of medical school all students devote much energy to concerns about specialty and training programs. Women students struggle with their own interests and weigh them against the realities of obtaining internships and residencies and of functioning in specialty roles. Often the field narrows because of the student's desire to feel accepted and needed rather than to continue to fight for recognition, as in a specialty such as surgery where hostility to women is considered great. Flexible training programs are not available in most specialties (psychiatry being a notable exception), even though many women as well as men suggest that part-time programs for some years may be more compatible with their life plans and will not interfere with their responsibilities for patient care.

It is impressive to see how many women do not recognize the pressures under which they operate and the compromises that they have made and continue to make. They feel guilty about making *any* demands on a profession that has been "generous" enough to accept them. Little anger may be expressed at this early phase because the woman represses or denies her perception of her second-class position when applying for internship or residency. Women often accept the "peculiarity" of their position as doctors, and they may share the prejudices of men in regard to their capabilities and the legitimacy of their career aspirations. The essential harmony between "feminine" role expectations and the caretaking activities of medicine is often ignored.

RECOMMENDATIONS

It seems both appropriate and necessary at this juncture to make some specific recommendations for nonacademically related additions to medical school programs:

1. Recruitment programs supported by medical schools to enlighten advisers and students in high schools and colleges about the possibilities of medical careers for women.

2. Women in administrative and faculty positions who are not only visible but available as advisers and friends, to meet with women students in groups or individually, as the need arises.

3. Flexible internship and residency training programs in all fields as well as within medical schools that would be available to *all* students. Limiting such programs to women is discriminatory to men who might also benefit from this kind of practice and would result in a second-class position for the woman physician.

4. Supports for women seeking training programs in areas not traditionally "feminine," such as the surgical specialties. Encouragement to continue and pressure by the medical school on training directors to accept women as house officers are necessary to help support women who risk rejection.

5. Active health programs with gynecologic and family planning services and psychiatric consultation. This not only is important for the health of the woman student but also communicates concern for her needs.

DISCUSSION

CORNELIA B. WILBUR, M.D. (Lexington, Ky.)—I would like to see a companion study to the study by Drs. Notman and Nadelson, on "Medicine: a Career Conflict for Men." Like the authors, I also have found that advisers in the school systems state that medicine is an unsuitable or unrealistic career for women. I do not know why some of these advisers (who are women) feel that this is so. Advisers, especially those in junior high schools or those who work with girls between the ages of nine and 14, are most responsible, since it is during these years that most of the women in medicine whom I have interviewed have made the final decision about their career. We have no way of knowing how many girls have been turned away by bad advice, except that of the 10,000 National Merit Scholars interested in going into medicine, one-third are girls.

All medical students look for ways of presenting themselves that will meet the requirements of the medical school and its interviewers. Fortunately, more women are presenting themselves to admission committees as young women wanting to have a career in medicine. Women are beginning to understand that their value in medicine is consonant with their being women and with their femininity. It is true that women medical students currently have too few role models for identification.

The larger part of my experience has been with women students in midwestern schools, and they do not feel that women students tend to withdraw in the class situation. Women students' reactions vary with their personality, but they do not necessarily hesitate to volunteer or respond because of problems of competitiveness. The women students with whom I have dis-

cussed this paper (about 34) do not feel that there is hostility directed at them from their peers; they do, however, feel that there is hostility from some of their instructors. Their most common comment is, "He is afraid of bright women." Women students in this medical school state that they do not feel that they are the targets of displaced anxiety. They recognize that men students frequently flirt with them, but with sex education for medical students there is more open discussion and a more comfortable relationship with male peers in the area of sexuality. Also, perhaps because a woman faculty member heads the sex course, women students do not admit to a need to appear disturbed in this area, and they do not admit to feelings of guilt about being in medical school. These may be differences between women in medical schools on the eastern seaboard and those in the Midwest.

There is clear recognition of the pressures under which women operate in medical school and in internship and residency programs and considerable expression of resentment when these pressures are not shared by their male colleagues. Women are quick to express hostility about problems among themselves and to other women in medical school if they feel the demands on them are greater than they are on their male colleagues. They do not feel that the medical profession has been generous to accept them, but rather that it has been fortunate to get them because they see the value of women as women in medicine. Nurturing capabilities make for easy adaptation in the clinical years.

Enlightened advisers at the junior high school level and beyond are vital. The possibility of flexible internship and residency training programs in all fields for all students is an interesting suggestion. It would seem only sensible for surgical training programs to accept women applicants on an equal basis with men, since women could be valuable in surgical specialties, as well as in general surgery.

Student health programs in undergraduate and medical schools should be sufficient to support women in medical school. Otherwise, these programs would have to be considered to be discriminating. There should be no necessity for special programs other than those which would be normally medically necessary for women at the college and professional school levels.

Having gone through medical school when there was active discrimination against women in medicine, without recourse such as there is today, I wholeheartedly support the recommendations made by Drs. Notman and Nadelson.

Women are not yet being accepted by medical schools on an equal basis with men. Constant, continuous, rigorous effort to achieve such a balance is of the utmost importance to medicine.

Women in Psychiatry: Past and Present Areas of Concern

BY NANCY A. ROESKE, M.D.

The APA Task Force on Women was created to study the special issues and problems of women, especially in relation to the practice of psychiatry, and the special concerns of women psychiatrists. In this paper, the author details the specific areas the task force is examining, summarizes the findings of some of the few reports in the literature, and outlines the projects the task force has undertaken.

AT ITS ANNUAL MEETING in 1972, the American Psychiatric Association appointed a Task Force on Women under the Council on Emerging Issues. The task force was created to examine two major areas: 1) special issues and problems of women in general, as those problems arise in the practice of psychiatry, and 2) special concerns of women psychiatrists. The 12-person task force[1] has had two meetings.

Before setting out in any given direction, the task force members decided to review the reports of previous APA meetings centered on women and to review the literature for articles relevant to its major areas of concern: activities of women psychiatrists, pay scales, working hours, academic and administrative positions, availability of part-time jobs, residencies that have special arrangements for mothers, provisions for reentry into professional life after childbearing, transference and countertransference problems of women psychiatrists, and women residents' professional handling of sexuality with peers and patients. The task force also seeks to encourage women APA members to participate more in their dis-

Read at a panel held at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Roeske is Director of Undergraduate Curriculum and Associate Professor, Department of Psychiatry, Indiana University School of Medicine, 1100 West Michigan St., Indianapolis, Ind. 46202, and Chairperson of the APA Task Force on Women.

[1] A list of the members of the task force appears in appendix 1.

trict branches and APA's working committees.

1966 APA MEETING ON WOMEN IN PSYCHIATRY

The training and functioning of women in psychiatry was the focus of a 1966 meeting in Philadelphia of the Committee on Manpower, chaired by Dr. Daniel Blain (1). The summary of this otherwise unreported meeting, like other reports in the literature, emphasized that some of the statistical information on women in medicine (and thus in psychiatry) has certain implications for women's functioning in this profession. It was noted that only seven percent of all physicians were women; 12 percent of psychiatrists were women. More women than men (approximately 18 percent) worked part time and more women than men worked for unremunerated hours. There were fewer women than men in psychiatry in such positions as consultant, teacher, administrator, and researcher.

While the percentage of women accepted into medical school has fluctuated over the years (though without any discernible trend), the total percentages of men and women accepted have been similar. In 1961–1962, out of all those who applied to medical schools, 63 percent of the women applicants and 60 percent of the men applicants were accepted. Thus the fact that there were fewer women in medical schools reflects the fact that fewer women applied to medical schools.

The participants in the 1966 conference noted that the advantages of psychiatry for women included the relative flexibility of one's schedule, the challenge of the work, the less frequently encountered prejudices toward women, the less physically demanding nature of the work, the possibility of regular hours, and the potential for capitalizing on the feminine characteristics of "mothering, intuitiveness, sensitivity, and gentleness."

The particular problems encountered by women in medicine were found in the area of social acceptance, where pressure against one's career choice by peers, superiors, and family was still prominent. Other social pressures mentioned included the stereotyping by the mass media of the woman as a homemaker and the questioning, rather than the sanctioning, of a woman's right to attend college. Other obvious problems included the lack of flexibility at all levels of training, linked with the higher rate of attrition of women in medical school, the absence of refresher courses for the inactive or temporarily less active woman in practice, the excessively long training period between entrance to college and the end of residency, and the role conflict, both external and internal, of wife versus mother, versus doctor, versus competitive peer, versus submissive woman, versus aggressive partner, versus companionate listener.

THE SELECTION PROCESS FOR PSYCHIATRY

The selection process for psychiatry formally begins with the admissions committee of the medical school. In 1970 Dr. Harold I. Kaplan (2) concluded a seven-year study on more effective recruitment and utilization of the talents of women physicians and on resistance to them. On the basis of an authoritative survey of women physicians by Dykman and Stalnaker (3) Kaplan estimated that 38 percent of the 17,000 women physicians in the United States had to remove themselves from professional activities for an average of four years because of pregnancy and family commitments. Thus the nation was deprived of 25,840 woman-years of medical practice.

Although the percentage of women among medical students in the United States increased from 4.5 percent in 1929 to 8.5 percent in 1961, the United States still lags far behind other countries in these percentages. Many reasons may be given for the disparity between America's utilization of women in medicine and that of the rest of the world. Dr. Kaplan explored the area of prejudice against women physicians on the part of medical educators and he found that there was a significant resistance to admitting women into medical school, whether they were single or married and whether they had children or not. Dr. Kaplan did not comment upon the fact that, in spite of their stated resistance, medical school educators admit the same relative proportions of women and men applicants.

The resistance to making adequate provisions for women once they are in medical school (that is, if they marry, have children, and encounter problems unique to women, such as childbirth and the care of children) is probably more professionally disruptive and distressing. Schools may refuse to provide any time off for childbirth, or they may insist upon rigid adherence to work or night schedules when minor modifications in these areas might allow a student who is a mother to successfully perform both functions. In fact, many medical schools have observed that women students usually return to school a few days after giving birth. This observation is used as a justification for the conclusion that, if they are motivated, women are capable of adhering to rigid educational programs, and the observation is used to confirm the absence of a need for special programs for physician-mothers. Dr. Kaplan's aforementioned advocacy of greater flexibility in medical education represents a criticism of the American model. Dr. Kaplan has stated that the enforcement of such a rigid system appears to seriously limit the recruitment of women into medicine. Using the example of foreign countries in which flexible provisions are made for women, Kaplan concluded that such flexibility is a major factor in encouraging more women to seek medicine as a career.

WOMEN IN MEDICINE

What kinds of women become physicians? A 1971 study by Dr. Phoebe Williams of 212 Radcliffe alumnae who had become physicians (4) supported earlier studies reported by Lopate in her classic book, *Women in Medicine* (5). The background of women physicians may be characterized as urban and affluent, their parents as

highly educated, and their fathers as professional men or businessmen. Dr. Williams reported that one-fifth of the fathers who were professional men were doctors. Among the most important factors named in choosing medicine as a career were an interest in the biological sciences, a desire to help people, and a wish to do something worthwhile in which the woman could function in an independent manner. This last theme appeared in several forms: wanting to have a career with challenge, needing stimulation, desiring work that would permit a high degree of individualism and continually test one's mettle, and, in general, finding enjoyment in that which does not come easily. Another strong motif in choosing medicine was the importance of a relationship with an adult who had been encouraging. This person may have been a relative, a doctor, a school science teacher, or a college professor. No matter who it was, it was always someone who provided hope and support in place of discouragement.

What kinds of concerns do women in medicine express? Dr. Williams found that the younger women, those who had graduated since 1950, expressed more concern regarding the problems of combining career and marriage and career and children than did women who had graduated between 1910 and 1950. Dr. Alice Rossi (6), in her 1965 study of the career choices of women college graduates, had found that women frequently do not go into medicine because it is perceived as too demanding a profession to combine with marriage and family responsibilities.

That a medical career is highly demanding cannot be denied. In addition to a long and arduous training period that produces strain and demands time, energy, and emotional reserves, the profession of medicine entails at least two areas of expectation that can have especially stressful consequences for married women. The first of these is that medicine assumes the character of a calling. Unusual dedication is expected both by the physician and by the public. The second is that physicians bear responsibility for peoples' lives, and the requisite knowledge and skills become obsolescent very rapidly. Since the stakes are very high, women doctors, like their male colleagues, set stringent standards for themselves, and they need continual involvement in the world of medicine.

Thus the critical areas mentioned by the women in the Radcliffe study were the conflicts involving such problems as the birth of children, obtaining adequate household help, caring for children, and stresses in the relationship with one's husband. These family-career conflicts and their resolution led half the women to reduce their career demands by working fewer hours, changing to a less time-consuming specialty, or giving up medicine temporarily.

Pennell and Renshaw (7) listed the distribution of women physicians in the various specialties in 1970. The majority of women physicians enter the four specialties of pediatrics, psychiatry, general practice, and internal medicine. Of the 2,942 women psychiatrists who reported, 43 percent worked full time in private practice, 25 percent were engaged in full-time hospital staff practice, 5.5 percent were engaged in the administration of psychiatry, and three percent were engaged in either teaching or research. Women in psychiatry constituted 12.7 percent of the 23,236 practicing psychiatrists.

PROJECTS OF THE TASK FORCE ON WOMEN

The Task Force on Women concluded, at the end of its first meeting in November 1972, that it had two major goals: 1) to function as a consciousness-raising group for both men and women in psychiatry and 2) to collect data on men and women psychiatrists that would delineate pertinent problem and conflict areas and to offer suggestions and recommendations for solving the problems. To these ends, the task force has initiated a number of projects that have had both immediate and potentially long-range effects.

1. The task force has written to all psychiatric journals to ask whether women serve on their editorial boards and what their policies are on the acceptance of articles about and by women. It has also been recommended to all journals that manuscripts be sent to reviewers without any identification of the author to see whether this practice will eliminate any covert or overt prejudice against either the sex or the relative status of the author.
2. The National Institute of Mental Health and the American Medical Association have been questioned about the extent of their utilization of women psychiatrists.
3. A talent bank of women in psychiatry has been established at APA headquarters. An article in *Psychiatric News* urged women to submit their curricula vitae to the talent bank, specifying their availability for a position (including any geographical preference) and their particular areas of interest and expertise. Institutions seeking to hire psychiatrists are urged to avail themselves of this list of women.
4. A member of the task force attended the Conference for Residency Training Directors and suggested that a course on the psychology of women be offered during residency training. The task force plans to review the curricula of currently offered courses and to make this material available to all interested training directors.
5. A monograph summarizing the literature about women in psychiatry and the psychology of women is being planned.
6. Questionnaires designed to explore the role of women psychiatrists in education are being prepared for departmental chairmen and training directors.

Both the literature regarding women in medicine and the transcript of the 1966 conference clearly indicated the need for women to be on the admissions committees of medical schools, for women to be active in counseling women who are considering dropping out of medical school, and for women to take an active role in revising medical school training programs so that they are more congruent with a woman's role as a mother. The chairmen of departments of psychiatry can play a vital role in exerting pressure to include women physicians, not necessarily women psychiatrists, in admissions committees of

medical schools. Furthermore, all women applying for psychiatric residency training should be interviewed by a woman as well as by a man and all known areas of present or potential conflict in marriage, family, and career should be reviewed with the applicants in the context of the demands of the residency training program.

PILOT STUDY OF THE TASK FORCE ON WOMEN

There is a paucity of literature regarding the characteristics of men and women in psychiatry. The task force therefore initiated a pilot study to obtain sociological data, information on motivational factors and concerns experienced before entering medicine and psychiatry, and data concerning sources of emotional support, principal employment, professional activities, marital and family status, and family-career conflicts and their resolution.

The sample was composed of 35 women and 35 men who are APA members. They ranged in age from 27 to 62 years. About 75 percent of both men and women were either the firstborn or only children. Parents and spouse were named as the major sources of emotional support for both men and women. The decision to enter medicine tended to be made earlier by the women than by the men. The fact that more women than men decided to enter medicine before high school or during high school implies strong family support for this career choice, but research is needed to test this hypothesis. In contrast, the women decided later than the men to go into psychiatry. This is congruent with the statistics cited by Dr. Leo Madow (1, p. 20) at the 1966 meeting, which showed that there were greater proportions of older women than older men in psychiatric residency training. This finding has implications for training and professional functioning and demands greater scrutiny.

Data obtained on the source of financial support for medical school and residency training did not reflect the findings of other studies, which have indicated that women in medicine do not accept scholarships because of the prospect of a negative dowry. Sixty percent of both men and women psychiatrists reported that their parents supported them through medical school. The chief source of support during residency training was from the training stipend. The major area of concern was not the problem of financing training, as reported in other studies, but rather the long-term commitment required.

In general, the men reported a lower level of concern about entering both medicine and psychiatry. On the other hand, the women had two major areas of concern: combining profession and marriage, and combining profession and children. This concern was expressed by almost fifty percent of the women respondents.

In regard to the factors that influenced their career choice, both men and women listed an interest in biological sciences, a desire to help people, and an interest in psychology. But women checked these items three times more frequently than men. Finally, 17 of the women, but only one man, acknowledged that having experienced an illness oneself was a motivating factor.

Only two of the 35 men and four of the 35 women were single; three men and four women were separated or divorced. Two-thirds of the respondents were married by the time they entered residency training. Three of the men and 13 of the women were married to physicians. Although both men and women psychiatrists became parents during college, medical school, and residency training, most of the men psychiatrists' children were born before or during their residency training. Twenty-two of the women psychiatrists' 44 children were born after the women had completed their residency training, while only nine of the men psychiatrists' 32 children were born after the men had completed their residency training. The women have handled the family-career conflict by reducing their career demands, working fewer hours, changing to less strenuous and less time-consuming areas of practice, or giving up the care of their children to a housekeeper or parent. A few gave up the practice of psychiatry temporarily.

This pilot study indicates few significant differences between men and women who enter psychiatry. The major focus of difference appears to center on the family-career conflict. Some of the women in this study appear to have resolved this by having fewer children during their training and/or by delaying family formation until they had completed their training. Thus two-thirds of the children born to these women physicians must have been born after the women were 30 years old, which would increase the risks for mother and child. These data support other studies which recommended that women should have the option of flexibility in professional training programs and that child-care facilities should be available. The validity of this assumption needs to be further tested in future questionnaires, since it is not known whether women psychiatrists would want such a program. There also needs to be further clarification of why women wait until late in medical school or until they are in another residency training program before entering psychiatry. Finally, the fact that two-thirds of the women were married to men who were not in the medical profession suggests that they are likely to face marital problems based on their husbands' lack of understanding of their dedication to their profession.

In conclusion, the Task Force on Women believes that we should begin now to consider changes in our training programs and vocational opportunities on the basis of our current knowledge of the conflicts that face women entering residency and practicing psychiatry. The number of women entering medical school is increasing. Approximately 13 percent of those entering medical school in the fall of 1972 were women. Psychiatry has had and should have a special appeal to women and a need to use the talents of women.

Training the Woman Resident To Be a Psychiatrist

BY ELISSA P. BENEDEK, M.D.

The author focuses on the problems of the woman resident and draws upon her own experience to illustrate her point that women are not accorded the same consideration as other minorities and that, for women, the residency period may be one of loneliness and misunderstanding. She observes that women have as much to learn from men as men from women and concludes that, if there are enough women staff members to make it possible, each woman and man in a residency program should have some personal supervisory experience with a woman staff supervisor.

PSYCHIATRIC RESIDENCY TRAINING is a long, arduous, and sometimes lonely postgraduate medical experience. Because of the specialized and unique nature of the training, psychiatric educators in charge of such programs have focused on the social and emotional problems that are involved in converting the novice first-year resident into a skilled psychiatrist. Such relevant issues as identity problems, the doctor-patient relationship, coping mechanisms, and learning problems have all been intensively and extensively discussed and reviewed (1, 2). Conspicuous by its absence, however, is a body of literature on the special problems of residency training for minority groups: residents from lower socioeconomic classes, foreign residents, and women.

After looking at the few articles already in the literature, this paper will focus on the special problems facing the woman resident as she enters psychiatric residency training. My intent is to share some of the unique experiences, thoughts, feelings, and recollections of a woman resident; to explore the common problems that women residents face; and to make recommendations on areas that psychiatric educators need to reexplore in order to better recognize and understand the unusual position of the woman resident. Such a reevaluation of traditional

Dr. Benedek is Associate Director for Training and Education, York Woods Center, Ypsilanti State Hospital, 3501 Willis Rd., Ypsilanti, Mich. 48197.

The author wishes to thank Mr. Norman Johnston and Dr. Christine Bieniek for their assistance in the preparation of this paper.

programs also offers the potential enrichment of the training experience of men residents by expanding their understanding of the psychology of women.

The problems faced by the woman medical student have been effectively and sympathetically described by Notman and Nadelson (3, 4). These young women explored a woman's admission to medical school, her student years, her development both as a woman and as a woman physician, and the academic and nonacademic pressures that women face. They ended their comments by discussing the tentative development of a woman student's specialty choice. They concluded that the choice of a specialty requires a compromise between the student's professional interests, her personal plans, and the available training programs. Kaplan, too, noted that personal plans are of importance in admission to medical school (5). In his 1970 report of a survey of the attitudes of American medical schools toward women medical students, he concluded that medical schools are simply resistant to admitting women, whether they are single or married, with or without children. They fail to make adequate provisions for women in school (e.g., if they marry and have children) and offer no help if students encounter problems unique to women (e.g., childbirth and care of children). Although these studies deal with women in medical school, many of the problems and experiences faced by the resident psychiatrist are the same as those faced by medical students.

THE FIRST HURDLE: ADMISSION

No one has openly admitted that there is a quota governing the number of women applicants who are accepted to a general psychiatry residency training program. If a quota exists, it is probably in the minds of training program administrators and is certainly not spelled out in program descriptions and brochures. Women applicants who are interviewed for a first-year residency position are forced, however, to wonder about quota systems. The applicants have already had recent experience with a quota system when they were admitted to medical school. Procedures for admission to residency programs vary, but most have in common a personal interview with a senior staff member and a fellow resident. As a woman applying for residency training, I wondered why all of my interviewers were men. Even though there were reputed to be women psychiatrists and residents on the staff, none of them was involved in the selection process for the training programs I considered.

For me, admission to residency was a *déjà vu* phenomenon. Notman and Nadelson (3) suggested that many women who apply to medical school ask themselves, "What do I have to be like for them to accept me?" As an applicant I felt I had to screen my answers carefully or I would find myself denied the right to a career in psychiatry. Selection interviews are, of course, conducted with different focuses by different clinicians. But during the course of all my interviews I was struck by the discomfort of my examiners as they questioned me about my career plans. Though their psychiatric training seemed evident as they attempted to be nonjudgmental, it was obvious that some of them enthusiastically approved and others disapproved of my responses when they asked me why I wanted to be a psychiatrist, what kind of psychiatrist I wanted to be, and where I intended to practice.

Their uneasiness was even more apparent as they tried to frame legitimate questions about the compatibility of a successful career in psychiatry and a successful marriage and family life. At the time I applied for my residency I had been married for three years to a young man who had an established professional career. My interviewers stumbled as they asked legitimate questions about my husband's career plans and especially about the possibility of future moves. A survey of my colleagues revealed that relatively few men were questioned about family plans but almost all women were.

The first hurdle on the road to training, then, is gaining admission to a high-caliber residency program. This requires expert skills on the part of the woman candidate in recognizing and dealing with the anxieties, challenges, and threats she presents to the men training directors simply because she is a woman. Of course, there are some training programs specifically tailored to women. One such program exists at the Department of Psychiatry of New York Medical College; it was instituted in 1962 as a special residency training program in psychiatry for physician mothers (6). The program allows women physicians with children to proceed in training by modifying the traditional routine of a psychiatric residency. While meeting the American Board requirements for psychiatry and neurology, women physicians are offered flexibility in scheduling and are given summer, Christmas, and Easter off to be with their families. But this is a specially designed program for mothers and, as such, seems to have all the advantages and disadvantages of a Seven Sisters women's college. A woman's perspective on issues is overemphasized, while the male viewpoint is missing. Women psychiatrists have as much to learn from their male colleagues as their colleagues have to learn from them, especially in the areas of child development and general psychology.

THE VICISSITUDES OF TRAINING

After admission to the average residency training program, the woman quickly finds that, although the programs have geared themselves to individualized training for some other minority groups, no special efforts have been made to recognize and deal with the problems of the woman resident. In a field that deals with the person as an individual, it is sad to see that few attempts are made to individualize training. Administratively, the new woman resident is not seen as an individual, or as different in any way from men residents, and no special provisions are made for combining career training with her nonprofessional life.

Residency training programs boast of the compatibility of general psychiatric training with psycho-

analytic treatment and work on advanced degrees at universities. It is possible to make special arrangements to pursue joint programs in psychiatry and public health. But the realistic problems for the woman resident, such as "on call" time, rooming arrangements, vacations, and holidays, are nonnegotiable issues. They are simply ignored. No special arrangements are suggested for the woman resident and she quickly recognizes resistance and a thinly disguised hostility if she calls attention to her "different" but parallel career development needs as a wife and mother. In the last year of my residency, during a planned pregnancy, I was shocked to find that my situation was viewed as unique, even though a colleague had been pregnant the previous academic year. The training institution had no administrative plans for a pregnant resident. My supervisors never commented on my pregnancy, the special needs I might have had because of my pregnancy, or how pregnancy would affect the staff and patients I dealt with.

In a typical program, a resident undergoing transition from the medical model to the psychiatric model finds support in peer groups and supervisors. The woman resident in the average training program frequently does not have peer groups; she left them behind in medical school. As a lone woman, she cannot share her anxieties and concerns since there is no one with whom to consensually validate her fears and insecurities. It takes a special effort to learn that many of her newly discovered conflicts come from the problems of being a psychiatrist and not from personal difficulties. Denial is a common defense that all residents use to avoid the anxieties of the first year, but the use of denial frequently disappears in the camaraderie of the peer group. The woman resident, because of her isolation and lack of peers, confuses the men residents' denial of anxiety with reality. An easy cop-out for men colleagues to use when denying anxieties is, "Oh, you are just being a silly girl." It is only after her residency training that she learns that the horrors of the first year are common and not unique to her, and that she is not the only one feeling anxious, uncomfortable, and totally inadequate.

Similarly, sexual feelings between men and women colleagues sometimes arise because of the closeness that is necessary in the peer group and because new residents are beginning to explore themselves more closely. The introspective woman, having been through the medical school experience in an almost all-men atmosphere, is better prepared to recognize and deal with some of these feelings than her men colleagues because of their limited association with women professionals. However, honest, open communication about these feelings, as well as other feelings between men and women that arise simply from sexual differences, is not common.

If women supervisors are available, they currently provide neither a peer group nor role models. Many of them have been trained in the era in which the psychology of women dealt exclusively with phases of the menstrual cycle and its psychological consequences (7). They have long been enmeshed in academic and professional struggles with their men colleagues and may frequently have been defeated or left on the lower end of the institutional structures. For example, the academic department of psychiatry where I had my training had women on its staff. Regardless of their professional expertise and qualifications, however, there was not a single woman above the level of instructor. In their decisions not to "buck the system," many of these women have disguised the very characteristics identified by society as being feminine that are most helpful in caring for people. Their empathy, kindness, and intuitiveness were defended against as they identified with male medical models and the supposed masculine values of aggressiveness, impersonality, and distance. I found no special sensitivity in any of my women supervisors to the problems of women residents and problems of women patients. They were, however, expertly skilled in "getting along with the establishment."

A woman resident certainly needs specialized supervision. The very fact that the resident is a woman brings issues to the forefront in all of her relationships with patients. There are common transference reactions that must be recognized and identified both by the patient and the therapist that occur simply because of her sex. Femininity is a constant reminder of past female figures. Typically, and in my own experience, the woman receives many requests for factual information about her previous training, her experience, and her own family. These requests hide different fantasies for different patients and must be explored on an individual basis. In my own experience, it was critical for many patients to verbalize their concerns about having a woman as a doctor before they could begin to place any therapeutic trust in me and start a relationship. Early in my residency training, a psychotic male patient propositioned me; his intent was not sexual but rather to form a relationship. Only years later was I able to recognize the true meaning of his crude advances. At the critical moment, when supervision would have made the difference, my supervisor stressed the importance of confronting this desperately ill patient with the reality of "I am your doctor, not your whore," rather than wondering with me what the patient was trying to tell me.

After a relationship is formed, other common themes must be recognized and explored. These include the questions of whether I have abandoned my family, whether I will abandon the patient, and what a "nice girl" like me is doing in such a crazy place as a hospital. Separation and termination are frequently colored by early fears of maternal abandonment. Of course, special events in the life of the woman therapist that cannot be and should not be avoided are common knowledge to patients. Such factors as marriage and pregnancy must be dealt with; the therapist needs both the supervision and the didactic material that can be given by sensitive and knowledgeable supervisors.

Previously, when I was discussing the lack of administrative accommodation for a woman, I cited my own experience during pregnancy. During the same pregnancy I was very sensitive to the fact that none of my supervisors discussed with me the effect that my pregnancy might

have on the child patients I was treating. Granted that none of these supervisors had been through pregnancy themselves, there was some literature that could have helped me understand the changes I was undergoing and their effect on my patients. No one made me aware of this literature and no one suggested that I use my experiences to add to it.

Residency training typically ignores the whole area of female psychology as it differs from male psychology. For example, there are special issues that are presented by women patients. We are only now beginning to recognize that the bored housewife syndrome is not necessarily psychopathology but a healthy response to a career as a chauffeur, maid, and jack-of-all-trades. Instead of pinning labels on women it may be appropriate to examine the reality of women patients' depression, boredom, anxiety, lack of fulfillment in life, and loss of identity. The plight of the woman patient is not adequately discussed in the psychiatric literature, and those in the best position to contribute to the literature on this subject are not encouraged to do so. The role of society in fostering psychopathology has long been recognized, yet all of the special problems that have been categorized in the past as affecting primarily men or women have not yet benefited from new psychiatric insights about the role of sexual stereotyping in mental illness.

The woman resident who has looked for and found no help from supervisors and peers will find none in seminars. The essence of the Freudian view of women, which permeates most seminars, is captured and caricatured beautifully by Natalie Shainess: "Women are passive, masochistic, more prone to jealousy, have weaker superegos than men and a weaker sense of justice. One of their major problems is penis envy, its hallmark being feminine aggression" (8). The alternate, more appropriate view of women that is proposed by Shainess—"Female psychology is the area which deals with the psychic components of gender and of the reproductive experience" (8)—is never taken into consideration. Child development, psychopathology, and psychotherapy are traditionally oriented and very few of the ideological concepts championed by the new femininist movement have sneaked into reading lists and seminar rooms. There are no seminars or tutorials on the developmental psychology of women. Contributions by Shainess, Bardwick (9), Miller (10), and Horner (11) and the whole proliferating literature on the development of women have not marked traditional residency training. It was only late in my career, after doing some original research, that a man supervisor recommended that I read Nelson's "Anlage of Productiveness in Boys' Womb Envy" (12). The study of the psychology of men and women—their similarities and differences—is critical, important, and enriching for all residents.

During residency training, besides learning to deal with individual patients, the resident must learn to work in a therapeutic milieu. There are many other problems that have to be recognized, confronted, and worked out if the therapist is to be successful. For a woman, the problems are compounded. The woman as a ward administrator is enmeshed in a host of old rivalries. The typical doctor-nurse, man-woman, father-daughter mold is broken. The sensitive woman doctor has recognized and dealt with these issues before, but new nuances come to play in a psychiatric setting. That is not to say that a man therapist does not have to recognize some of these issues ("We nurses deal with the patient 24 hours a day; who are you to tell us what to do when you only see them one hour in therapy?"), but ground has been covered for them by previous men residents and they need not always be pioneers.

CONCLUSIONS

In this era of reexploring and reevaluating traditional institutions, residency training should be scrutinized to see whether in fact it teaches all of the trainees the things that they need to know in order to practice psychiatry after graduation using their own special skills. Such reevaluation should especially look at the role of women in a psychiatric residency. I suggest that training directors reevaluate both the administrative makeup of training programs and the program content. It is certainly possible and advisable to provide enough flexibility in the traditional coeducational residency training program that all residents can pursue their personal and career goals. At the very least, modified schedules can be provided for women who are pregnant, giving them adequate antepartum and postpartum time off, at no cost to their careers. But even more desirable would be a form of parental leave that would be available as a choice to both men and women residents. It is critical that seminars and patient material be reevaluated and reworked to provide additional dimensions of consciousness to residency training programs. If there are available women staff members, each woman and man resident should have a personal supervisory experience with a woman staff supervisor.

As more and more women enter medicine, we can predict that the percentage of women who enter psychiatry will increase and the percentage of women available to treat and teach will similarly increase. Professional educators are obligated to improve the quality of the educational experience these young women will encounter and to make it as meaningful, relevant, and enriching an experience for them as for their men counterparts.

Women in Psychiatry

ALTHOUGH THERE HAS RECENTLY BEEN AN IMPETUS for women to engage in business and professional careers, obstacles to their full participation continue. These obstacles are in part related to traditional attitudes toward women that require reexamination. The difficulties that confront women who seek a career in psychiatry are the subject of a special section in this issue of the *Journal*.

Like all women who desire to develop their skills, women in psychiatry are troubled by the barriers that limit their performance and achievement. That there are obstacles to women's participation is indicated by the paucity of women engaged in the practice of psychiatry and the very small number who are prominent either in academic or policy-making circles. The limited number of women who are professionally effective can be accounted for, in part, by the reluctance of men to accept women as peers and by the hesitation of many women to assert themselves. Both these attitudes have been fostered by the lingering belief that women are or should be passive and therefore are unsuited for occupations that require energy and initiative.

The assumption that by nature woman is passive, which often serves as a rationalization both for men who fear the independence or competition of women and for women who doubt their ability, is based on limited observation and inaccurate interpretations of women's roles. Careful examination of women's behavior and psychology indicates that much of what has been considered passive is better understood as active and receptive. Homemaking is an active task that requires a woman to exercise intelligence and to be receptive to the needs of those for whom she cares. In the past, women have tended to accept passively—although not always without frustration—the role of homemaker as their sole occupation. Changes in patterns and conditions of homemaking have made time and energy available for women who wish to use their talents and skills outside the home.

To deal with the issue of how best to utilize the available talents of women, it is necessary to scrutinize their experiences and accomplishments as they enter various fields in increasing numbers. At the same time, it is essential to refine our ideas about gender-linked attitudes in order to provide an atmosphere in which women can be most productive. Our concepts of activity, passivity, and receptivity require clarification. Do these attitudes differ fundamentally in women and men, or is it rather that they have been expressed differently because anatomical and physical differences have been interpreted in such a manner as to lead to markedly different role assignments? The association between activity and aggression and the stress on the hostile nature of aggression to the neglect of its adaptive aspects have confused the issue. In the course of their work with both men and women, psychiatrists can gather information that is essential if we are to truly understand the psychology of both women and men.

The capacity to bear children poses a problem for women who wish to pursue a career but who do not want to forego the experience of motherhood. We are in the process of examining our patterns of child care and of education and training for women in this situation with a view toward developing programs that will most effectively allow

In this section, the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

women to make their contribution to society and at the same time provide the necessary care for their families.

Women in all fields have assumed leadership in delineating the inequities that have burdened them, in calling attention to the underutilization of their skills, and in offering proposals to correct discrimination against them. Their efforts have been recognized and there has been a positive response in society at large as well as in the psychiatric profession. Interest within the profession is exemplified by the establishment in 1972 of the APA Task Force on Women, chaired by a woman, and by the publication in this issue of the *Journal* of several papers by women on the subject. These events and the large and enthusiastic attendance by both men and women at the May 1973 APA meeting of the Task Force on Women is an encouraging beginning. We look forward to the increased participation of women in the affairs of our Association and to contributions from both women and men that will help to resolve some of the issues pertaining to the roles of both men and women in our profession and in society at large.

REBECCA Z. SOLOMON, M.D.

Dr. Solomon, a member of the Editorial Board of The American Journal of Psychiatry, *is in private practice in Hartford, Conn., is Senior Clinical Associate in the Department of Psychiatry at Yale University, and also teaches at the Institute of Living, Hartford.*

Benjamin Rush: Morality in Government

> It is absolutely necessary that our government . . . should possess . . . the moral faculty, and the conscience of an individual. Nothing can be politically right, that is morally wrong. . . . Virtue is the living principle of a republic.

SO WROTE the American Psychiatric Association's patron saint, Dr. Benjamin Rush, in 1786.

In 1973—in this year of doubt about morality in government and while the American citizenry questions the credibility of its leaders and holds its breath in suspense to see whether its republican system can steady itself in the face of unprecedented insults—it is timely that an essay on morality by a founding father of the nation, who happens also to be the father of American psychiatry, should be republished.

Under the title *Two Essays on the Mind* (1) APA Fellow Eric T. Carlson, M.D., has reproduced from the original printings two little-known lectures by Rush that reveal his thinking on the influence of physiological causes on the moral and intellectual faculties of man. Dr. Carlson has provided an introduction that places the works in their 18th-century perspective. Here was a signer of the Declaration of Independence who wanted to design a system of government that could endure all the faults and foibles of the men who participated in it, investigating the moral nature of man from a medical viewpoint.

The year 1786, when Dr. Rush delivered "An Enquiry Into the Influence of Physical Causes Upon the Moral Faculty" before a distinguished audience of the American Philosophical Society, which included Benjamin Franklin, was a turbulent year of monetary inflation and political crisis; it was after Yorktown but before the adoption of the United States Constitution. Rush felt that the time was right to submit to the leaders of government "this feeble effort to increase the quantity of virtue in our republic."

"I am aware," he said, "that in venturing upon the subject, I step upon untrodden ground." He was aware that medical writers had never before attempted to include disorders of the moral faculty in their system of nosology, and as a consequence physicians had not attempted to treat such disorders as medical conditions that might be improved or cured with proper remedies. His foray into the area of personality disorder became the pioneer American attempt both to study moral derangement and to regard it as a medical disorder deserving of treatment. For the first time, an American physician—not a preacher or a philosopher—claimed the subject of morality as his proper province.

In summary, Rush theorized that human beings are born with a moral faculty just as they are endowed with certain native intellectual faculties. The moral faculty is the power of the mind to choose good or evil, virtue or vice. The moral faculty should not be confused with conscience: "The moral faculty performs the office of a law-giver, while the business of conscience is to perform the duty of a judge." It can be affected by climate, diet, sleep, disease, music, and numerous other physical and social factors.

Rush considered that he "only performed the drudgery of a pioneer" in opening the subject to medical research, and he hoped that others would pursue it: "The moral faculty has been the subject of less culture and fewer experiments than the body, and the intellectual powers of the mind. . . . Should the same industry and ingenuity, which have produced . . . triumphs of medicine over diseases and death, be applied to the moral science, it is highly probable, that most of those baneful vices, which deform the human breast and convulse the nations of the earth, might be banished from the world." Rush did not consider it impossible that some day researchers might discover medicines that would influence the moral faculty: "May not the earth contain in its bowels, or upon its surface, antidotes to our moral, as well as natural diseases?"

It was his conviction that treatment could be effective. This led Rush in later years to write against capital punishment and on behalf of the rehabilitation of criminals. He founded the Pennsylvania Prison Society to promote prison reform. But he never believed that laws or prisons would promote virtue: "Laws for the suppression of vice and immorality will be as ineffectual, as the encrease and enlargement of gaols."

What would guarantee the proper development of the moral faculty in man? Rush had an answer: "There is but one method of preventing crimes, and of rendering a republican form of government durable, and that is by disseminating the seeds of virtue and knowledge through every part of the state, by means of proper modes and places of education." His advice to the guardians of American liberties was "to establish and support public schools." Only public education could guarantee that moral government would endure in a republic.

It is nearly 200 years since Rush opened the field of morality to medical enquiry. We physicians have not eagerly embraced it as our province. The day seems very distant when moral responsibility, and more particularly morality in government, will be within the purview of medicine. Rush would have encouraged us to move forward: "I am fully persuaded that . . . it is possible to produce such a change in the moral character of man, as shall raise him to a resemblance of angels." The simple, sometimes naïve, but perspicacious thoughts of our 18th-century psychiatric forebear are worth reflecting on today.

BRIEF COMMUNICATIONS

Drug Treatment of Depressed Patients Referred for Hospitalization

BY JOEL KOTIN, M.D., ROBERT M. POST, M.D., AND FREDERICK K. GOODWIN, M.D.

The authors' clinical impression that many depressed patients are admitted to hospitals without having received adequate drug treatment as outpatients was confirmed with a sample of 51 depressed patients. Of these, only 20 percent had received proper drug treatment before referral. The authors propose a larger study of the actual patterns of drug prescription to seek the causes of inadequate treatment.

THE DEVELOPMENT of effective antidepressants has been one of the major psychiatric advances in the last quarter century. Yet it has been our experience in a number of different clinical settings—including university, public, and private hospitals—that many depressed patients are referred to hospitals without adequate trials of antidepressant medication as outpatients. There are several possible explanations: a physician's bias against drugs, the use of the wrong drugs, the use of inadequate dosages of the correct medication, or an emergency that requires hospitalization.

As a first step toward investigating this phenomenon, we undertook a retrospective study of 51 consecutive depressed patients who were admitted to our research unit that is studying affective illness. The study focused on the drug treatment that the patients were receiving at the time of their referral and their subsequent response to treatment in the hospital. This paper reports the results of the study and discusses possible explanations and remedies for the situation.

At the time this work was done, the authors were with the Section on Psychiatry, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, Md., where Dr. Kotin was Clinical Associate, Dr. Post is Special Research Fellow, and Dr. Goodwin is Chief, Clinical Research Unit. Dr. Kotin is now Assistant Adjunct Professor, Department of Psychiatry and Human Behavior, University of California at Irvine; his address is 1201 West LaVeta Ave., Orange, Calif. 92668.

METHOD

The charts of all patients who were admitted for depression over a two-year period (February 1970–February 1972) were reviewed to determine what drugs they were receiving before their admission and their response to the drugs they received in the hospital, and to obtain various demographic data. All patients met standard criteria for a diagnosis of primary affective illness (1); their level of depression at the time of admission ranged from moderately severe to severe (global depression rating of eight or more on a modified version of the 15-point Bunney-Hamburg scale [2]).

RESULTS

Fifty-one depressed patients ranging in age from 19 to 74 were included in the study. There were 28 women and 23 men. Twenty-nine were unipolar (no history of mania or hypomania) and 22 were bipolar (history of mania or hypomania).

The pattern of drug treatment at the time of referral to the hospital is summarized in table 1. Although 21 patients (41 percent of the sample) were receiving tricyclic antidepressants (imipramine, amitriptyline, or doxepin), only eight patients were receiving tricyclics at dosages of 150 mg./day or greater; 13 patients received dosages of 100 mg./day or less. The period during which the patients received antidepressant drugs varied in length considerably (five days to one year; mean=73 days), but this factor was not considered in evaluating the adequacy of this treatment. Of the 21 patients receiving tricyclics, 13 were also taking other psychotropic drugs. Of the 30 patients not receiving tricyclics (59 percent of the sample), nine were receiving psychotropic drugs that

TABLE 1
Drug Treatment of Depressed Patients at the Time of Their Referral (N=51)

Drug	Number	Percent
Tricyclic antidepressants*		
150 mg./day or more (including five patients taking additional psychoactive drugs)	8	16
50–100 mg./day (including eight patients taking additional psychoactive drugs)	13	25
Lithium carbonate (including one patient also taking phenothiazines)	2	4
Phenothiazines and/or other psychoactive drugs, excluding antidepressants	9	18
No medication	19	37

*Imipramine or amitriptyline, except in the case of one patient who had received doxepin.

are not ordinarily considered antidepressants (five were taking phenothiazines). Two patients, however, were receiving lithium carbonate. Nineteen patients were not taking any medications before admission.

The source of the referral (psychiatrists in private, clinic, or hospital practice, and physicians other than psychiatrists) did not seem to be related to the dosage of tricyclic that was prescribed. However, of the five patients referred by nonpsychiatrists, four were receiving drugs that are not ordinarily classed as antidepressants.

The following examples are typical of patients with severe depression who were treated with drugs other than antidepressants (case 1) or with low dosages of antidepressants (case 2) before hospitalization.

CASE REPORTS

Case 1. A 35-year-old attorney had been seen in psychotherapy sessions twice a week for more than two years for symptoms of depressed mood and inability to work. Nine months before his admission, his therapist had prescribed 300 mg. of thioridazine a day for agitation; he had later increased this to 400 mg./day. A psychiatrist on the NIH staff saw the patient in consultation and recommended hospitalization. On admission, the patient displayed a marked dyskinesia with a coarse tremor and dysarthria. All medications were discontinued after admission and within a week the tremor had disappeared, the patient's speech became normal, and his anxiety had decreased. The patient later responded to 250 mg. of imipramine a day after approximately ten days of treatment.

Case 2. A 27-year-old woman became depressed following the birth of her first child. She felt overwhelmed by her responsibilities, was disgusted by the soiled diapers, and resented the interruption of her career. She consulted a psychiatrist and was given 50 mg. of amitriptyline twice daily and thioridazine as necessary. Her depression worsened; two months later she was hospitalized and given six sessions of electroconvulsive therapy, with a "fair" response. Three months later she took an overdose of her medication and was again hospitalized. Shortly thereafter she was referred to NIH for more prolonged treatment. At NIH she remained depressed for two months while receiving intensive psychotherapy and lithium carbonate. After this period, she received 250 mg. of amitriptyline a day for three weeks and became much more positive about her abilities, her child, and her home situation. Her daily ward depression ratings improved significantly and she was discharged a week later after having her dosage reduced to 200 mg. of amitriptyline a day.

Only 35 percent of the patients in this study received tricyclic antidepressants while hospitalized at NIH, primarily because our current research focused on various experimental compounds and lithium. However, of the 18 patients who did receive tricyclic antidepressants, 12 responded,[1] an effect comparable to that reported in most studies (3).[2] Of the 12 in-hospital responders only two had had outpatient treatment at dosages of 150 mg./day or greater.

DISCUSSION

Evidence from a large number of controlled studies indicates that the tricyclic antidepressants imipramine and amitriptyline are in most cases effective in the treatment of moderate and severe depression only at dosages of 150 mg./day or greater (3). Of the 21 patients in our sample who received these drugs before their admission, only eight were receiving dosages in this range; 13 were receiving dosages of 100 mg./day or less.

Although there is some evidence that phenothiazines and related neuroleptics can be effective in relieving the agitation and anxiety that accompany some depressions (5), these compounds are not generally considered drugs of choice in the treatment of depression per se, especially if given alone. Nine patients in our sample were receiving these neuroleptic drugs without an accompanying antidepressant.

In drawing conclusions from these data, we have considered the treatment of moderate to severe depression to be "adequate" if patients were receiving tricyclic antidepressants at dosages of 150 mg./day or greater or were receiving monoamine oxidase inhibitors or lithium carbonate before their referral. Of the 51 depressed patients referred for hospitalization, only eight were receiving adequate tricyclic treatment and only two were receiving lithium. Therefore, by these criteria only ten patients (20 percent of our sample) were receiving adequate drug treatment for depression at the time of their admission. Twenty-two (43 percent) were receiving inadequate drug treatment and 19 (37 percent) were not taking medication.

Since the Clinical Center at the National Institutes of

[1] Nine of the 12 were unipolar; three were bipolar.

[2] Other antidepressant responses in the hospital included those of 17 patients who received lithium carbonate (these were predominantly patients with bipolar depression [4]), five who received electroconvulsive therapy, and one who received tranylcypromine. In the remainder of the sample, improvement was not clearly related to drugs.

THE AMERICAN JOURNAL OF PSYCHIATRY

Community Mental Health Services in Britain

BY DOUGLAS BENNETT, M.D., D.P.M.

Although the practice of psychiatry was similar in the United States and Britain during the last century, since then their paths have diverged, especially since the Second World War and the institution in Britain of the National Health Service. The major postwar development in Britain has been in social psychiatry, with particular reference to hospitalized psychotic patients. More recently, plans have been made to close mental hospitals and shift the locus of inpatient care to the general hospital. Projections have been made to provide services on a sector basis, in which teams of psychiatrists, nurses, and social workers serve population groups of 60,000 each and provide outpatient and transitional facilities as well as inpatient care. The author compares the different approaches in the United States and Britain and notes that, while neither can provide an ideal service, both can learn much from the differences.

WHEN WE IN BRITAIN use the word "community" in a mental health context, we are referring to care given outside the mental hospital in the mythical world of well people (1). We may include, too, the prevention of hospital admission and the idea of district or sectorized care. In the United States, "community" in a mental health context seems to have more to do with localism and the idea that services are better managed at the community level. I have heard it suggested that this view, which may have been inherited from Utopian thinkers of the 18th century, now reflects a dislike of the direct provision of services by the state (2). Whether that is so or not, it does emphasize the fact that since "community mental health" is deeply rooted in the history and the beliefs of our respective societies, it also has different meanings for both of us.

In trying to explain something of community mental health in my country I must try to make these differences clear. But I shall also try to avoid dangerous comparisons, for in the worldly wisdom of Samuel Johnson, "by exciting emulation and comparisons of superiority, you lay the foundations of lasting mischief; you make brothers and sisters hate each other." That I do not want to do.

Read as a special lecture at the 126th annual meeting of the American Psychiatric Association, Honolulu, Hawaii, May 7–11, 1973.

Dr. Bennett is Psychiatrist, the Bethlem Royal Hospital and the Maudsley Hospital, Denmark Hill, London SE5 8AZ, England.

OUR INHERITANCE

In the 19th century the practice and problems of psychiatry were very similar in our two countries. We both had our reformers. You had Dorothea Dix, who believed in the value of the mental hospital. We had John Conolly, who, by abolishing physical restraint, did much to improve our care of the mentally ill. Many before him had thought that the physical restraint of the mentally disordered could and should be reduced, but no one thought that it was possible to abolish it completely (3). Conolly's action in doing this led to great controversy, for he was eager that the mentally ill should be treated with the same good intentions as doctors treated the physically sick. Whatever we think now about equating mental disorder with illness, at that time it did much to better the social position and to increase the freedom of the mentally sick. So it is not surprising that Conolly also believed that mental disorders should be treated, whenever possible, outside the mental hospital. It took some time for his ideas to be accepted and their full impact had to wait on later social changes; I cannot tell the whole story.

In the latter part of the last century and in the first half of this one, matters moved forward rather sedately. Then the shared dangers and experiences of the Second World War drew people of all classes in our society closer together. By the end of the war it was accepted that it was the proper function of government to ward off stress and strain not only among the poor but among all classes of society. Sir William Beveridge's plan to combat the evils of want, disease, ignorance, squalor, and idleness was implemented in a series of enactments that led to what we now call the Welfare State. In an attempt to deal with

disease, the National Health Service was established as one limb of this body.

Some see our Welfare State as helping the disadvantaged to make good; others see it as undermining people's self-sufficiency by state handouts. But whatever one's opinion of its effect on the wider society, its egalitarian philosophy of "bread for all before cake for anybody" has had a very considerable influence on the provision of services for the mentally ill. In the National Health Service, which came into being in 1948, psychiatrists (like other doctors) were salaried. They received the same pay as the surgeons and internists wherever they worked. The service brought all the hospitals, whether general or mental, formerly managed by local bodies, under the same regional and national direction. As soon as these hospitals were administered side by side the difference in the quality of care given to the mentally disordered and the physically ill was shown up in bold relief. Also, the difference in the terms under which people were eligible for treatment was so great that quite soon the whole question of legal commitment was referred to a Royal Commission (4).

Their enquiry and recommendations led to a new Mental Health Act, which was passed by Parliament in 1959. This act made it possible for the mentally ill person who could accept the role of patient to be admitted to a hospital without the formality of commitment. Committal, when needed, was no longer a quasijudicial process. Instead, two doctors, one a qualified psychiatrist, had to explain why care or treatment was needed and why the individual could not be treated in the role of a voluntary patient. Today less than 17 percent of admissions to our psychiatric hospitals are compulsorily committed, and only six percent of hospital residents are detained in this way. The Royal Commission also stated the view that greater efforts should be made to avoid hospital admissions. Its report gave official recognition to those community psychiatric services which had already been developed up and down the country and encouraged a further use of out-of-hospital care.

PRESENT THINKING

In the words of one American visitor: "The major postwar development in British psychiatry has been in social psychiatry, with particular reference to psychotic patients in hospital. By contrast, in the United States, a major development has been in so-called dynamic psychiatry, with particular reference to ambulatory neurotic patients" (5). Knight Aldrich thought, quite rightly, that our pattern of care was a direct outcome of the National Health Service, an origin that has influenced its subsequent development.

Since both the mental hospitals and the general hospitals are managed by the same regional hospital boards, the planning of community psychiatry services has been undertaken in a medical context. This was Ministry of Health policy, and in 1960 its Chief Medical Officer, Sir George Godber, urged that "if the opportunity for bringing psychiatry fully into the general pattern of medicine which now presents itself is grasped, the new attitudes created both within the profession and in the public mind, will do more for mental health than any other single measure" (6).

At that time the Ministry of Health was encouraging the development of psychiatric outpatient, day-patient, and inpatient services in general hospitals but still thought that a substantial part of hospital psychiatric work would have to be undertaken in the traditional mental hospital. More recently the department has decided that improvements in treatment and care allow us to replace the large separate mental hospitals with a service based in the general hospitals. This is a dramatic change in policy. In such a service the general hospital psychiatric unit will combine with the other two parts of our three-part health service—that is, the family doctor and public health sectors—to provide comprehensive psychiatric care to a defined district. The Department of Health intends that these facilities should be used as flexibly as possible and that emphasis should be given to rehabilitation and to the preservation of continuity in the patient's personal relationships and his contacts with his local community (7). There are hopes that these three parts of the medical services can plan more effective comprehensive care when, next year, they are merged and administered by area health boards.

This is the rhetoric; you may wonder by how much it is separated from reality. There is of course a gap, but it may be narrowing rather than widening. It should be filled in part by a newcomer to our services: the social services department of the local authority. This new body grew out of the appreciation by the social workers and government that the existing social services were responsible only for certain types of social problems and the difficulties of particular age groups (8). It was felt that human needs could not be categorized in such an arbitrary fashion in spite of the realization that medical care, education, and housing all have social components. So it was decided that social workers should give up such former specialisms as mental health, child care, and welfare and merge these into one department providing a unified family service. Social workers accepted this, integrated their professional associations and their differing trainings, and, when sanctioned by the Social Services Act of 1971, took charge of their own departments in the local authorities.

While some people regret the disappearance of the former mental health and psychiatric social workers, the new departments provide a useful social counterpoise to our medically oriented psychiatric services. But the departments are young and are preoccupied with their own internal problems, so it will be some time before the social workers can make their full contribution to community mental health. Meanwhile, many psychiatrists say that the removal of social workers from the medical orbit has made effective cooperation impossible (9). Since there are plenty of examples of fruitful cooperation between psychiatrists and social service departments, these remarks only show that many doctors do not know how

to work for and with social workers. The doctor's outlook has some importance, for the next stage of our planned development is the closing of the mental hospital, and that requires teams of social workers, psychiatrists, and others to work together to meet the needs of a specified population. The administrative discontinuity between health and social service departments must make teamwork difficult, although with the right attitudes this could be overcome.

CLOSING THE MENTAL HOSPITAL

The arguments for closing the mental hospital have never been very clearly stated. In the 1950s community care was seen as preventing admission, or, failing that, securing the patients' early discharge from the hospital. Such a policy was community minded only in the sense that it was anti-institutional. Not surprisingly, a comparative evaluation of three dissimilar services, including a community service with a worldwide reputation, did not confirm the value of this limited type of community care (10). In spite of this as well as great and well-known achievements of some of our mental hospitals, they have remained the villain of the piece in community mental health. Many people feel that the continuing accumulation of patients in these ghettos has cast a shadow over all our services and mocks our therapeutic pretensions.

Some argue that we cannot get rid of our mental hospitals before we have adequate alternative services. Certainly we have an increasingly clear idea, in numerical and other terms, of the alternatives that are needed (11). Others believe that alternative services will not be provided as long as the mental hospital remains as a convenient way to dispose of difficult problems.

We know that as long as we have mental hospitals we are unlikely to prevent admission to them. Hopes that this would happen have always overlooked one important aspect of psychiatric care: the desire of mental health professionals to get rid of undesirable patients. This distinction is almost unique to psychiatry and reflects an intolerance rooted in the inability of doctors and others to deal with their own feelings, whether of hostility, anxiety, or a sense of failure (12).

There are many ways of tackling the problem, but the fundamental solution is that professional staff members have to give up the right to refuse referrals and the right to refuse to refer people to other services (13). In practice, undesirable patients are referred in only one direction, whose final destination is the mental hospital. Elimination of the mental hospital does not solve the problem entirely, for with or without the mental hospital, both doctors and social workers may refer unwanted patients to colleagues with lower status or less training (14). But the taking apart of mental hospitals will force the staff to look for other solutions and to rethink the real nature of psychiatric care.

Part of the hospital dismantling happens naturally, for in our country, as in yours, there is a steady attrition of long-stay hospital patients by discharge or death and only a slow accumulation of new chronic patients (15). Simultaneously, new patients have to be diverted to other services and in particular to the district general hospital. There are dangers for the mental hospital. The knowledge that the hospital is going to close can lead to a sharp decline in staff morale, which results in a deterioration in standards of care. To avoid this it is proposed that the mental hospital's catchment area should be split into geographical districts of 60,000 population. Then each district will be served by a team made up of district general hospital and mental hospital staff members and social workers from the new departments. The beds and day places in both the mental hospital and the district general hospital will be divided, so that each team has day places and beds in both situations (7). When eventually the new general hospital psychiatric department can provide all the necessary services, the few patients remaining in the mental hospital will be transferred to another mental hospital whose closure program is less advanced. This is an ambitious plan and progress must be slow, for evolution, not revolution, is the aim. Even so, reaction—especially from doctors—has been quite brisk.

DOUBTS AND DIFFICULTIES

In such a situation reality and rhetoric tend to drift apart. I have already introduced you to what Titmuss (16) called "that exotic hothouse climbing rose, 'the welfare state,' with its lovely hues of tender pink and blushing red, rampant and rampaging all over the place, often preventing people from 'standing on their own feet,' in their own gardens." He went on to wonder whether the everlasting cottage garden trailer "community care" did or did not conjure up a sense of warmth and human kindness essentially personal and comforting. It may have done so, but it has conjured up controversy and criticism too. Doctors hold strongly partisan views for or against community psychiatry; these have been thought to have a distinctly American flavor (17). But these views are equally evident in Britain. I suspect that the flavor is neither British nor American, but medical.

The public, on the other hand, seems to welcome the community approach. They have always cared for the mentally ill, and it is only in quite recent years that they have begun to trust the mental hospitals to do this for them. Of course the mentally ill were not always well cared for outside the hospital. However, a national opinion poll in 1971 showed strong public support for undertaking the care of the mentally ill in the community (18). Six out of every ten people interviewed thought that the mentally ill should be encouraged to lead a normal life. At the same time, the public openly discusses and criticizes conditions in mental hospitals that previously were not mentioned in the press (19). Meanwhile some psychiatrists, seemingly forgetful of recent scandals, revive nostalgic memories of mental hospital gardens with their flowers and green lawns and speak of them as a sanctuary for patients (20).

While the debate continues, community psychiatry has

not provided a ready banner for those in our islands demanding social change or marching in a radical activist cause (21).

More substantial doubts have been expressed about the government's plans. The statistical projections of change in bed needs and the experiences of a few community services are critically questioned, for it is on these rather doubtful data that the plan seems to be based (22–24). The success of the plan in its present form depends on certain assumptions "which have not yet been tested; that very few patients will in future become severely handicapped psychiatrically, that those who do so will either not require residential care or can be looked after adequately by the social services and that the disadvantages apparently inherent in the mental hospital system will not be inherent in any system which replaces it" (11).

It does seem that the number of hospital beds allowed in the plan may be too low. It seems, too, that little or no thought has been given to the needs of that small number of patients, mostly with schizophrenia or organic mental syndromes, who still become handicapped in spite of all we do. Obviously there will be difficulties in establishing effective cooperation between psychiatric units in the district general hospitals and the new social service departments that, between them, will have to provide the shelter and the rehabilitation services that were the mental hospitals' special contribution to the care of chronic patients. There are doubts, too, not only about how they will cooperate, but how each will meet its own responsibility. Some wonder whether the social service departments can provide these facilities, or whether they can provide them in time.

It is important that the provision should be kept in phase with the transfer of medical services from the mental hospital to the district general hospital. Doctors doubt whether the general hospital, for its part, can cope with patients whose problems are difficult or chronic. It is assumed that because general hospitals have dealt only with the less severely ill, that is all they can do. This is not so, but of course they will have to change their ways of functioning and they will need support from other services as well as accommodation in hostels, boarding houses, and day centers for those with permanent handicaps.

THE PRESENT SITUATION

It is unlikely that the scheme in its present form will meet all these needs, and evaluation of the services is essential. There is ongoing evaluation of some developing services, and other evaluations are projected (11). The findings, taken together with the experience of clinicians, should lead to later modifications of the government's policy.

It will be clear from this account that our present mental health services are still largely centered on the hospital and the psychiatrist. Our major aims are the prevention of chronic patienthood and the closing of the mental hospital, rather than primary prevention, consultation, and crisis intervention. This outlook is in part an expression of our pragmatism and in part determined by the history and the logic of our situation. Having recognized that with the means at our disposal we could not prevent mental illness or prevent some patients from developing very severe handicaps, we decided that we would deal with what was within reach not only of our understanding but of our resources. In time we shall do more for mental health than for mental illness and be more interested in communities than hospitals. At present, manpower is limited and so are budgets; this has an effect on what is done.

There will be three psychiatrists (and only one of those a senior) for the population of 60,000 persons that is the basic unit in our planning. This population will yield about 500 patients who are in our care at any one time while approximately another 500 people, 215 of them inpatients and about 265 outpatients, will come into care each year (25). They will be supported by hospital and public health nurses and by social workers. There will also be about 24 family doctors in the area. These doctors, however, cannot give psychiatrists much help, for in our health service family doctors are already seeing the bulk of the patients with socio-emotional problems (26). These patients suffer mostly from minor affective illnesses that are associated with various forms of social difficulty (27). The family doctor's interest in his patients' socio-emotional difficulties and his capacity to deal with them are closely related, whether by cause or effect, to the size of his practice (28). He refers those with the more difficult and time-consuming problems to the psychiatric outpatient departments and is often reluctant to support them after they are discharged from the hospital. Many solutions have been proposed: these include giving family doctors more education and understanding of socio-emotional problems and reorganizing their practices on a group basis with social workers attached. While matters are slowly changing, we know that many family doctors are still not keen on working with social workers (29).

When people suggest, as many do, that we cannot meet the requirements of a community-based mental health service with our present resources, they overlook the fact that the redeployment of these resources, if it does not improve the situation greatly, is unlikely to worsen it. Staff morale can have a considerable effect, and it seems clear that the morale of mental health personnel is higher when they work outside mental hospitals. At the same time we are uneasily aware of the increasing demand on services that are separate from mental hospitals. Also, the scope of psychiatry's responsibilities is more broadly defined. It is no longer enough to provide for the needs of the mentally ill, the mentally retarded, and disturbed children. We have to provide more service for mentally disturbed offenders, mentally infirm old people, alcoholics, drug addicts, and those who attempt suicide and self-poisoning.

It seems obvious that if we are to meet all these new demands, our tasks and responsibilities will have to be reallocated. A service based on sectorized care has certain advantages in this respect, for the sector defines the responsibility of psychiatrists and others who have to

share the patients' care. It forms a base for cooperation with families and with a range of services providing social help whose very existence is undreamed of by many hospital psychiatrists. Even today, district services have provided some working or living environments for those persons who are severely handicapped by mental illness and who lack family support. There are not enough, but they are there and provision for them is growing. Of course, sectorization does not ensure that the psychiatric and social services will cooperate. So much has been said and written about continuity of care, cooperation, coordination, and teamwork that the words have all but lost their meaning. They do not tell us how to work or what to do. They provide no basis for teaching psychiatrists. Many still think that community psychiatry is nothing more than keeping the patient out of the mental hospital, giving first aid care, talking to a social worker, or sending the patient to a day hospital. Some believe that community services allow psychiatrists to escape the painful business of facing up to the patient's problems. Nothing could be farther from the truth.

THEORY AND RESEARCH

There is much more to community mental health services than their administrative structure. It takes more than goodwill, common sense, and enthusiasm to provide effective help. Meyer Gross said many years ago that "advances in mental health are not made by administrative dodges or by giving new names to old problems." Some old problems are always with us, and none is more teasing than the balance of advantage and disadvantage between treatment in the hospital or in the community. There is no right or wrong solution, only better or worse decisions for certain people, at certain times, and in certain circumstances. Yet we cannot learn how to make those decisions, modify our services, or teach others unless we have a sound basis in theory and research. While community psychiatry must have a practical base in a sectorized service, its theoretical foundation is in social psychiatry. Sabshin brought these two facets together when he said that community psychiatry uses social psychiatry's techniques, theories, and methods, as well as those of the other behavioral sciences to meet the mental health needs of a defined population over a significant period of time (17).

It is one of the little-known strengths of the British community mental health service that we have a small but influential group of research workers in social psychiatry. Their work grew out of the Medical Research Council's Social Psychiatry Research Unit, which was founded by Sir Aubrey Lewis in 1948—the same year that the National Health Service was established. Their research and their names are well known (30). They have influenced plans and policies and have provided guidelines in matters of patient management, rehabilitation, and social treatment.

It is still difficult to attract first-class clinicians from the hospital to community mental health. The view that they will come to us only when they see that community mental health has scientific substance is reflected in the remarks made by a young American lecturer working with us. "It is this emphasis on the scientific validation of delivery systems and treatment techniques which lends respectability to the movement and makes community psychiatry a proper pursuit within the university" (31). But trainees must not learn only about community and social psychiatry. They have to learn to be community psychiatrists. Training in community psychiatry requires that the student work in a situation where the patient and his family remain the staff's responsibility over a considerable period of time. The community psychiatrist does not learn by working in private with highly selected patients who are "his" alone. He has to learn through the sobering experience of sharing with a team the care of those who may be poor, unintelligent, or poorly motivated or who may fail to improve with treatment (32). The knowledge that there is no escape from this responsibility and that the team's failure to help the patient involves them in his long-term care concentrates the mind wonderfully and leads to more ingenious and useful solutions. The resulting growth of staff confidence and competence is another factor that is rarely taken into account yet is crucial to the future function of our community mental health services.

In Britain, at least, community psychiatry is not a soft option, offering "less painful jobs at higher salaries, with high sounding titles, plus opportunities for community contact, the novelty of newspaper interviews and speech making" (33). I doubt whether it is like that in America either. For wherever we work, our methods differ and our failings and our excellences differ. Neither of our two countries can provide the ideal service. One hopes that we can learn something from our differences.

Questions of the Month

Directions: Each of the incomplete statements below is followed by four or five completions. Select the *one* that is BEST in each case.

Question 1 The sudden and repeated cessation of a person's train of thought or speech in the middle of a sentence (blocking) is most characteristic of
(A) children in latency (7–11 years)
(B) psychotically depressed patients
(C) schizophrenic patients
(D) patients with Korsakov's disease
(E) patients with manic-depressive psychosis

Question 2 Myoclonic jerks or generalized convulsions with paroxysmal activity on the electroencephalogram may be observed prior to drug withdrawal when high daily dose levels have been attained during chronic intoxication with
(A) heroin
(B) methadone
(C) cocaine
(D) pentobarbitol (Nembutal)
(E) meperidine (Demerol)

(The Questions of the Month are from APA's Psychiatric Knowledge and Skills Self-Assessment Program: A Stimulus to Self-Learning. The answers are supplied on page 1081. The references for the questions are supplied on page 1117.)

Epidemiological Differences Between White and Nonwhite Suicide Attempters

BY ANDREAS M. PEDERSON, PH.D., GEORGE A. AWAD, M.D., AND ALAN R. KINDLER, M.B.B.S.

Using the Monroe County (N.Y.) Psychiatric Case Register, a stable data source, the authors attempted to determine differences between white and nonwhite suicide attempters, to identify the factors that are associated with self-destructive behavior in both groups, and to determine the subsequent mortality rate among suicide attempters. They found a number of differences between whites and nonwhites and conclude that the motivation for suicide, the techniques used to treat attempts, and the degree of risk of further psychiatric difficulty may be different for the two groups.

DURING THE PAST SEVERAL YEARS an increasing amount of research on suicide and suicide attempts has been conducted (1). Many of these studies have focused on the relationship between suicide and suicide attempts (2, 3), while others have focused on the clinical course and outcome of persons who have attempted suicide (4). A number of these studies have outlined basic demographic characteristics and some psychological factors associated with people who attempt suicide; however, the epidemiological study of suicide attempts is one major area of investigation that has only recently begun to be examined systematically (5).

Although our knowledge about suicide attempts has increased considerably, a number of questions about the factors associated with persons who attempt suicide remain unanswered. Part of this is due to the unreliable data collection systems that are used to record attempted and accomplished suicides in most communities. Another problem is that many of the previous studies on suicide attempts have used relatively small or highly selected samples. For example, most have included only those suicide attempts which have been identified by admission to general hospitals or by reports to the police. Because of the variability in data collection systems and because different sample selection procedures have been used, conclusions based on comparisons of these studies are of limited validity.

Further, while there is evidence to suggest that patterns of suicide attempts and characteristics of attempters are different in white and nonwhite populations (6, 7), little work has been done to investigate these differences in a systematic manner. These differences could produce considerable variance in studies of attempted suicides, particularly with certain types of sample selection procedures. More importantly, however, if race is not examined as a separate factor, true differences between white and nonwhite groups, which may indeed be helpful in understanding attempted suicides, may go unnoticed.

We attempt in this paper to clarify some of the problems found in previous research through an epidemiological study of suicide attempts in a relatively stable population over a four-year period. By examining the differences between white and nonwhite suicide attempters and outlining the demographic characteristics of suicide attempters, we hope to identify the characteristics associated with high-risk groups in terms of self-destructive behavior and to provide some insight into the underlying motivations for a wide range of self-destructive and potentially suicidal behavior. In addition, we will investigate the number of deaths among these suicide attempters in a five-year follow-up period, looking particularly at those deaths attributed to suicide.

METHOD

The sample consists of all consecutive suicide attempters treated in the emergency department of Strong Memorial Hospital during the years 1964 through 1967. Strong Memorial Hospital, the teaching hospital of the University of Rochester School of Medicine and Dentistry, is the largest general hospital in Monroe County, New York. During this study period the average yearly number of patient contacts in the emergency department was about 55,000. Every suicide attempter or suspected attempter who was treated in the emergency department was seen by a psychiatric resident before discharge. This contact was then reported to the Monroe County Psychiatric Case Register.

The Monroe County Psychiatric Case Register was used to identify the characteristics of the suicide attempters seen during the study period. The register was started on January 1, 1960, and nearly every psychiatric contact made in Monroe County has been reported to it since

At the time this work was done, the authors were with the Department of Psychiatry, University of Rochester School of Medicine and Dentistry, 260 Crittenden Blvd., Rochester, N.Y. 14642, where Dr. Pederson is Assistant Professor of Psychiatry and Psychology and Drs. Awad and Kindler were residents in psychiatry. Dr. Awad is now Associate, the Clarke Institute of Psychiatry and the Psychiatric Service of the Provincial Court (Family Division), Toronto, Ont., Canada, and Dr. Kindler is Associate, Department of Psychiatry, University of Toronto.

The Monroe County Psychiatric Case Register was supported from 1960 to 1969 by Public Health Service grant MH-00381 from the National Institute of Mental Health and is currently supported by the New York State Department of Mental Hygiene, the Monroe County (New York) Board of Mental Health, and the University of Rochester. This work was supported in part by these funds and by Public Health Service grant MH-08469 from NIMH.

then (8). In addition to basic demographic data about each patient, diagnoses, including the designation "suicide attempt," are recorded for each psychiatric contact, along with an indication of the presence or absence of previous psychiatric care. The register also records the deaths and their causes for every person who has been reported. This procedure creates not only a continuing psychiatric register but also a continuing and updated death register. In the register, race is categorized as white or nonwhite. The white group includes all Caucasians and most of the Puerto Rican and American Indian ethnic groups, while the nonwhite group is composed almost exclusively of people of Negroid ancestry. The socioeconomic level of a person who is reported to the register is defined by the census tract in which he lives. Each census tract in Monroe County has been classified into one of five groups (from I at the highest to V at the lowest) on the basis of a composite index of social and economic factors. These factors and the method of classification have been described elsewhere (9).

Out of 219,233 emergency room contacts at Strong Memorial Hospital during the study period (1964 through 1967), 1,345 persons were seen as the result of a suicide attempt. While there were five other hospitals with emergency services in the Rochester-Monroe County area during the study period, Strong Memorial Hospital had nearly twice as many emergency room contacts per year as any other, and it was the only hospital that had a psychiatric facility in the emergency department. Because of its range of services and psychiatric facilities, most suicide attempts in the county area were referred to Strong Memorial Hospital. Examination of the emergency log from another large general hospital, which ranked third in the number (121, 266) of total emergency room contacts during the study period, revealed that only 125 suicide attempts had been treated in its emergency department.

Unlike samples used in many other studies of suicide attempts, this sample has the advantage of including all consecutive suicide attempts seen in an emergency department; it consequently provides a wider range of suicidal behaviors, from the mild suicide gesture to the relatively serious attempt. Also, because most of the suicide attempts in the county were treated at Strong Memorial Hospital, the sample is fairly representative of all suicide attempts made throughout the county.

TABLE 2
*Age-Specific Average Annual Rates for Suicide Attempts by Race and Sex**

Age Group	White		Nonwhite	
	Male	Female	Male	Female
0–14	1	2	10	5
15–24	90	238	153	803
25–44	49	129	67	436
45–64	21	44	0	87
65 and over	18	13	0	62
Crude rate	29.91	74.34	48.82	266.08

*Rate is the number of attempts per 100,000 based on the 1960 census of Monroe County.

RESULTS

Of the 1,345 suicide attempts recorded at Strong Memorial Hospital during the study period, 335 (25 percent) were made in 1964, 347 (26 percent) in 1965, 313 (23 percent) in 1966, and 350 (26 percent) in 1967; the yearly average number of suicide attempts was 336. The total number of completed suicides in Monroe County for the four-year period (obtained from county health statistics) was 244, an average of 61 per year. The ratio of suicide attempts treated in our emergency department to completed suicides for the four-year period was 5.5:1. These figures represent an annual rate for suicide attempts treated at Strong Memorial Hospital's emergency department of 57.30 per 100,000 and a county suicide rate of 10.4 per 100,000 for each year of the study period.

Table 1 presents the total group of suicide attempters by age, race, and sex. Eighty-eight percent (1,186) of the total sample were white and 12 percent (159) were nonwhite. Women accounted for 74 percent (1,000) of the total. Eighty-four percent (1,128) fell within the group aged

Total		323		863		22		137		1,345	

15 to 44. In the white group, 73 percent (863) were women and 27 percent (323) were men, a ratio of approximately 3:1. However, in the nonwhite group, 86 percent (137) were women and only 14 percent (22) were men, a ratio of 6:1, which is quite different from that of the white group. Age also differentiated the white from the nonwhite group. While 82 percent (978) of the whites were between 15 and 44 years old, 94 percent (150) of the nonwhites were in that age range. There was no nonwhite man older than 45 in the study group.

Table 2 presents the age-specific average annual rates for suicide attempts by race and sex. The combined rate for whites was 52.91 and that for nonwhites was 159.57; the overall crude rate was 57.30. In every age group where nonwhite suicide attempts were recorded, the rates were higher for the nonwhites than for the whites. This is especially obvious for the nonwhite women in the groups aged 15 to 44. Even when the overall rates were adjusted for age, the differences remained; the age-adjusted rate for nonwhite women (268.12) was nearly four times that of white women (74.19), and similarly the rate for nonwhite men (44.87) was approximately 1.5 times the rate for white men (29.68). In some cases, the reported rates are based on relatively small frequencies, since only a few suicide attempts were recorded in some age groups and the total number of nonwhite suicide attempts was relatively small in terms of overall frequency.

Table 3 presents the socioeconomic levels of the suicide attempters in the sample. As can be seen, levels IV and V were overrepresented. These two levels accounted for 33 percent (449) of the attempters but represented only 19 percent of the total county population. Although socioeconomic levels I and II accounted for 38 percent of the total county population, only 28 percent (382) of the sample was from these two levels. In the white group, persons from socioeconomic levels IV and V represented 27 percent (315) of the attempts, while in the nonwhite group 84 percent (134) were from these two levels. In contrast, socioeconomic levels I and II accounted for 32 percent (377) of the white attempters but only three percent (five) of the nonwhites.

The relationship of marital status, race, and sex of the suicide attempters is presented in table 4. Examination of the marital status in terms of race and sex revealed that only 38 percent (61) of the nonwhite suicide attempters were married compared with 50 percent (594) of the white group. Among nonwhite men, 55 percent (12) of the suicide attempters were single and among the nonwhite women 28 percent (39) were separated. These two rates are in marked contrast to those for the white group and appear to account in large part for the different rates of married people in the white and nonwhite groups.

The relationship of psychiatric diagnosis given at the time of the suicide attempt to race and sex is presented in

TABLE 4
Suicide Attempts by Marital Status, Race, and Sex

Total	323		863		22		137		1,345	

table 5. Individuals who had a diagnosis of psychotic disorder (schizophrenia, affective psychosis, or organic brain syndrome) represented 16 percent (212) of the total group. The diagnoses of neurotic disorders or character disorders made up 64 percent (867) of the total sample. Most of the 11 percent (154) classified as "other" received a diagnosis of adjustment reaction. For the remaining eight percent (112), there was no psychiatric diagnosis other than the recorded suicide attempt. Examination of the relationship of diagnosis to race revealed that for the total group of suicide attempters the diagnosis of psychotic disorder was made more frequently for the white group than for the nonwhite. For the white group, 25 percent (79) of the men and 13 percent (117) of the women were diagnosed as psychotic, while for the nonwhites ten percent (two) of the men and ten percent (14) of the women received a diagnosis of psychotic disorder. The other psychiatric diagnoses given to the nonwhite and white women were similar; however, nonwhite men received proportionately more diagnoses of neurosis or were more often classified as "other" than white men.

Table 6 presents the relationship of psychiatric care received by the suicide attempters to race and sex. Looking at this factor in terms of race, among 30 percent (353) of whites the suicide attempt represented the sole psychiatric contact, while this was so for 52 percent (82) of the nonwhites. And although 62 percent (738) of the white patients received care at some time after their attempt, only 43 percent (69) of the nonwhites received care subsequently. The differences in total psychiatric care were also striking when the white and nonwhite groups were examined by sex. For the men in our sample, 78 percent (252) of the white group, compared with 50 percent (11) of the nonwhites, had received some psychiatric care either before or after the attempt was made; all of the nonwhite men and all but 22 of the white men received care after the attempt. Among women, 67 percent (581) of the whites and 49 percent (66) of the nonwhites had received some psychiatric care either before or after the suicide attempt; for all but eight percent (73) of the whites and six percent (eight) of the nonwhites, care was received after the attempt.

As shown in table 7, three percent (35) of those who attempted suicide from 1964 through 1967 had died by the end of 1968; 51 percent (18) were women. All of the deaths in the nonwhite group were among those aged 25 to 44. In the white group, 52 percent (16) were men and 48 percent (15) were women. Ten of the deaths were attributed to suicide. In fact, suicide was the largest single cause of death in the sample and yielded a crude rate for those who attempted suicide of 595 per 100,000 per year. This is 57 times higher than the rate of 10.4 per 100,000

TABLE 6
Suicide Attempts by Psychiatric Care Received, Race, and Sex

per year for suicides in the general population. Of the suicides, three were men and seven were women; eight occurred in persons aged 25 to 44 (two of the men and six of the women). Examination of the suicides by race revealed that no nonwhite deaths were attributed to suicide.

DISCUSSION

Many of the results of our investigation support the findings of previous research. The overall ratio of women to men (3:1), the age distribution, and the marital status of our sample of suicide attempters are all in general agreement with the findings of other studies that have been conducted on this subject (10).

In our sample, we found a suicide attempt rate of 57.30 per 100,000 per year and a ratio of attempted to completed suicides of 5.5:1. If we take into account estimates of the suicide attempts that were treated at other hospitals in Monroe County, we obtain a suicide attempt rate of 74.69 per 100,000 per year and a ratio of attempted to completed suicides of 7.2:1. Even these must be regarded as underestimates, for, as Mintz (5) and others have suggested, many suicide attempts are probably never reported or treated in hospitals.

The overrepresentation of the lower socioeconomic levels in our sample, among both whites and nonwhites, lends support to the finding that the emergency services of general hospitals tend to be used more by the lower classes (11). This overrepresentation suggests: 1) that the suicide attempt rate is higher for people in the lower socioeconomic levels, 2) that they are treated for a wider range of self-destructive behavior than people in other classes, or 3) that people from the upper and middle socioeconomic levels may be treated for suicide attempts in places other than emergency departments of general hospitals, e.g., a private physician's office.

Ninety-two percent of our sample received a psychiatric diagnosis at the time of the suicide attempt; however, relatively few were diagnosed as having a psychotic disorder. For many, the suicide attempt appeared to be only one aspect of more general psychopathology, for some it appeared to have contributed to their receiving psychiatric treatment in the future, and for others it appeared to be the result of a single stressful or disorganized period.

Our study also points out major differences between whites and nonwhites who attempt suicide. Although Hendin (12) has suggested that the rate of completed suicide is higher for younger nonwhites than it is for whites and some suggestions have been made in the literature concerning the higher suicide attempt rates for nonwhites, relatively little has been done in the past to systematically examine racial differences. The data from this investigation suggest that white and nonwhite groups who attempt suicide are two distinct populations that may require different predictive, intervention, and treatment methods. The rate of attempts by nonwhites was 160 per 100,000 per year, compared with 53 per 100,000 per year for whites. The ratio of women to men for nonwhites was 6:1, in contrast to the ratio of 3:1 for whites. The nonwhite group was also younger and more often came from the lower socioeconomic levels. Marital status also separated the whites from the nonwhites. Although the majority of attempts in both groups were made by married or single persons, nearly a third of the nonwhite women were either separated, divorced, or widowed and more than half of the nonwhite men were single. In addition, fewer nonwhites had received psychiatric care either before or after the suicide attempt and nonwhites were less often diagnosed as having a psychotic disorder than whites.

These results could be interpreted as reflecting a lesser degree of psychological disturbance in the nonwhite population, as well as a difference in motives and dynamics between the whites and nonwhites who attempt suicide. However, the data could also be interpreted as reflecting different patterns of care or access to treatment for the nonwhite and the white groups. The lower proportion of nonwhites who received care before and after the attempt could be the result of the availability of fewer facilities to nonwhites or of the reluctance of nonwhites to use existing psychological services or to follow through with referrals. The data could also reflect different diagnostic biases on the part of mental health professionals, or even a "screening-out" process that may selectively exclude nonwhites from treatment. Further research is needed to determine which factors or combinations of factors are involved in these observed differences in diagnosis and patterns of care between the white and nonwhite groups.

There was also a noticeable difference between white and nonwhite groups in the incidence of completed suicide. The high risk for suicide in the suicide attempt group is most impressive among whites. Also of interest is the relatively young age at which the suicides occurred and the relatively short time span between the suicide attempt and the successful suicide. Although nonwhites accounted for 11 percent of the total number of deaths, none was due to suicide, while 32 percent of the white deaths were. This result is somewhat surprising since, for the total county population, nonwhites have a suicide rate of 8.98 per 100,000 per year while the rate for whites is 10.51 per 100,000 per year. Since nonwhites who commit suicide do not as often have a history of attempts, the attempts may not be as predictive of future suicides as they are for whites. For whites, the suicide rate among those

who had previously attempted suicide was much higher than that for whites in the general population. The rates for completed suicide among white suicide attempters were 743 per 100,000 per year for white men and 649 per 100,000 per year for white women, yielding an overall crude rate of 675 per 100,000 per year. This contrasts with an overall rate of 10.51 per 100,000 per year for suicides by the white population of the county as a whole. These findings suggest that among whites the likelihood that a person will commit suicide after an attempt is nearly 64 times as great as for someone in the general population. For nonwhites, however, suicide attempts appear to be negatively related to further self-destructive behavior. These results tend to support the conclusion that the nature of the suicide attempts of whites and nonwhites form two distinct patterns and should not be looked upon or investigated as a common problem with similar motives or prognoses.

This study indicates that people who attempt suicide can be differentiated by race in terms of demographic characteristics, diagnosis, psychiatric history, and the incidence of subsequent successful suicide. It further points out that even though relatively few nonwhites may be treated for suicide attempts compared with whites, the rates of suicide attempts in the nonwhite population are much higher. When treating people for suicide attempts, the physician may note differences between whites and nonwhites in the motivation for the attempt, the treatment techniques that are required, and the degree of risk for further psychiatric difficulty and/or suicide. It is vital that professionals working in the emergency services of general hospitals who deal with people from the lower socioeconomic classes, as well as with proportionately greater numbers of nonwhites than whites, be aware of these differences. In future research on suicide attempts, it would seem imperative to consider race as a separate factor. Not only are there clear differences between the groups but, when the groups are considered together, little information about the nonwhites is uncovered, since there is a relatively large ratio of white to nonwhite suicide attempters in most communities.

A Survey of Physicians' Attitudes and Practices Regarding Erotic and Nonerotic Contact with Patients

BY SHELDON H. KARDENER, M.D., MARIELLE FULLER, AND IVAN N. MENSH, PH.D.

An anonymous questionnaire survey of a random sample of 460 physicians revealed that most psychiatrists, obstetrician-gynecologists, surgeons, internists, and general practitioners did not believe in the efficacy of or engage in nonerotic physical contact with their patients. Five to 13 percent of the respondents indicated that they engaged in erotic behavior with patients and five to 7.2 percent engaged in sexual intercourse specifically. The authors point out the need for greater openness and acceptance of discussion about and research in this highly sensitive and vital area.

THE HIPPOCRATIC OATH'S inclusion of an injunction against seducing one's patients clearly delineates this as an age-old concern of physicians. In practicing the art of medicine, doctors have been ethically obliged to judiciously distinguish between transmitting care, comfort, and reassurance in the "laying on of hands" or else transgressing into nontherapeutic or antitherapeutic practices. A combination of factors, including long-standing cultural taboos regarding the discussion of sexual matters, a need to maintain the idealized image of the physician growing out of a priest-practitioner heritage, and rampant ignorance due to a lack of adequate research, have contributed to the maintenance of mythology in all matters sexual. Where there is no fact, fantasy and fallacy flourish.

The historic (1) initial efforts by Ellis, Krafft-Ebing, Freud, Van de Velde, Kinsey, and, currently, Masters and Johnson have attempted to dispel ignorance by providing knowledge that prepares the physician to be of help to his patient. But is the physician, who is subject to the same cultural forces of sexual repression as his patient, prepared to be of help? In order to meet this challenge an increasing number of medical schools in the United States have instituted courses of instruction in the management of sexual disorders (2, 3). With this heightened focus of attention, there logically follows a recrudescence of old concerns regarding the role of the physician himself in relation to his patient.

Reactions to therapists who advocate sexual intimacy as therapeutic (4, 5) have been swift, strenuous, and condemnatory. Others (6–10) have written urging that while such responses may be appropriate, they should be the outgrowth not of blind reaction but rather of serious considerations and open-minded contemplations of the ethical, moral, and therapeutic issues involved, which allow for honest exploration of the question of sexual relations between physician and patient. They point out that guidelines for conduct are blurred and uncertain, as demonstrated by the introduction of each new therapeutic maneuver, i.e., nude marathons, "feeling" therapy, encounter groups, and emergence of a new morality. Further, these authors acknowledge the absence of and need for open discussion, critical appraisal, accumulation of a data base, and honest attempts to develop measures of therapeutic effectiveness.

It is within this spirit of scientific inquisitiveness, which acknowledges both the emotional sensitivity of the subject matter and the absence of existing data, that a pilot study was initiated to determine attitudes and practices of physicians regarding the use of nonerotic and erotic contact with patients.

METHOD

A 32-item, one-page questionnaire was designed that inquired about the respondents' age, years in practice, marital status, and the extent to which they attempted to treat sexual problems in their practice. Six questions followed that asked about their beliefs and practices regarding nonerotic contact with patients. Similarly, seven questions inquired about erotic contact with patients. Respondents were then asked to specify the actual number of patients involved in erotic contact excluding and including sexual intercourse. A final space allowed for other comments. Erotic behavior was specifically defined as that behavior which is primarily intended to arouse or satisfy sexual desire. Most of the questions, except for subjective and demographic ones, were to be answered by circling "0" (never), "1" (rarely—defined as less than five percent of professional experience or opinion), "2" (occasionally—less than 25 percent), "3" (frequently—more than 50 percent), or "4" (always). Two questions required replies specifying the actual number of patients with whom the respondent had had erotic contact.

The authors are with the Department of Psychiatry, School of Medicine, University of California at Los Angeles, Center for the Health Sciences, Los Angeles, Calif. 90024, where Dr. Kardener is Adjunct Associate Professor, Ms. Fuller is Research Associate, and Dr. Mensh is Professor of Medical Psychology.

Computer assistance for this work was obtained from the Health Sciences Computing Facility at UCLA, which is funded by Public Health Service grant RR-3 from the Division of Research Resources, National Institutes of Health.

A total of 1,000 male physicians were selected by random sampling from the membership list of the local county medical society (N=approximately 10,000). The study sample represented the five specialty groups of psychiatry (P), obstetrics-gynecology (OBG), surgery (S), internal medicine (IM), and general practice (GP), with 200 physicians in each group. The questionnaires identified only the respondents' specialty and were otherwise totally anonymous. Each was mailed with an explanatory cover letter and a stamped, addressed return envelope. The physicians' responses were tallied and the data studied by contingency table analysis (Biomedical Program BMD02S). Chi-square tests were used to determine significant differences between the groups thus analyzed.

RESULTS

General Data

Forty-six percent of the physicians responded (N=460). Four questionnaires were defaced with derogatory or profane comments. There were three letters of complaint that objected to the study and alluded to a (never specified) number of additional physicians who were offended. The questionnaire was sent only to male physicians and did not distinguish between homosexual and heterosexual relationships, since the study concerned itself with attitudes toward eroticism generally. In order to preserve anonymity, the only identifying characteristic known to the investigators was specialty. Therefore this is the only information available regarding nonrespondents.

By specialty, 25 percent of the respondents represented psychiatry (N=114); 23 percent, general practice (N=105); 19 percent, internal medicine (N=89); 18 percent, obstetrics-gynecology (N=83); and 15 percent, surgery (N=69). Chi-square tests indicated a significant difference among the five specialties' response rate ($p<.01$). Forty-two percent of the total respondents were 40 to 49 years old (N=194), and 33 percent were 50 to 59 years of age (N=151). Twenty-six percent reported being in practice for 11 to 15 years (N=117), 31 percent for 16 to 24 years (N=144), and 20 percent for 25 years or more (N=93). Eighty-six percent were married (N=393), three percent (N=14) single, eight percent (N=34) divorced or separated, and three percent (N=14) widowed. (Five respondents did not answer the question about marital status.)

There was a significant difference ($p<.05$) between the number of respondents who reported no prior marriages (81 percent, N=221) and those with one or more prior marriages (19 percent, N=51). The frequency distribution of those with no prior marriages was as follows: surgeons, 96 percent (N=44), obstetrician-gynecologists, 85 percent (N=39), internists, 81 percent (N=46), psychiatrists, 75 percent (N=46), and general practitioners, 74 percent (N=46).

In response to the question "Do you attempt to treat sexual problems in your medical practice?" the five groups responded in significantly different ways ($p<.01$) (table 1). This was due primarily to the differences between psychiatrists and obstetrician-gynecologists as compared to surgeons.

Nonerotic Behavior

Table 2 presents the data obtained in response to two questions regarding nonerotic behavior. Psychiatrists and obstetrician-gynecologists were significantly different in their beliefs, as compared to their internist and general practitioner colleagues ($p<.01$). Practice paralleled beliefs regarding nonerotic behavior with patients, again distinguishing psychiatrists, obstetrician-gynecologists, and surgeons from internists and general practitioners ($p<.05$). The response to questions regarding who initiates such practice indicated that, if it is the doctor, he will most likely be an internist or general practitioner ($p<.01$). Except for the nine percent (N=38) of the physicians who were frequently or always the initiator, all specialties reported that it was most often the patient who

TABLE 2

initiated the nonerotic contact, less often was it mutually initiated, and least often by the physician.

In response to the question "Do you believe such behavior would be misunderstood?" significant differences ($p<.05$) existed among the specialties ($N=430$). This was due primarily to the difference between psychiatrists, 69 percent ($N=94$) of whom believed that it would occasionally, frequently, or always be misunderstood, as compared with 40 percent ($N=66$) of the internists. The distribution of responses for the other specialties believing such behavior would occasionally, frequently, or always be misunderstood is as follows: obstetrician-gynecologists, 59 percent ($N=64$), general practitioners, 51 percent ($N=66$), and surgeons, 48 percent ($N=53$).

A subjective-response question asked under what circumstances nonerotic physical contact (holding, hugging, kissing) might be beneficial. Of the physicians responding, 74 percent ($N=184$) recognized the value of such behavior, particularly for providing comfort and in giving tangible support to a patient. The major specialty group explaining the value of this behavior were psychiatrists, 71 percent of whom ($N=53$) in previous responses (table 2) were shown to be least likely to believe in or to engage in nonerotic behavior with their patients.

Erotic Behavior

The data in table 3 indicate responses to several questions regarding erotic behavior with patients.

Erotic behavior other than intercourse tended to consist primarily of kissing; less often of manual or oral stimulation of the patient's genitals; rarely, such stimulation of the physician's genitals; and least of all, mutual genital stimulation.

To the open-ended question "Under what circumstances might erotic behavior be utilized in treatment?" 87 percent ($N=193$) of the respondents reported that it is never of benefit. Their statements included comments on ethical proscriptions, destructiveness to the doctor-patient relationship, dangerous loss of physicians' objectivity, injunctions in the Hippocratic oath, and comments that such behavior was "censurable," "unforgivable," and constituted "professional suicide" or was prima facie evidence of severe psychopathology in the physician. Explanations for the usefulness of erotic practices were offered by 13 percent ($N=28$) of the respondents and included such statements as "improves sexual maladjustments," "helps patients' recognition of their sexual status," "especially in the depressed, middle-aged female who feels undesirable," "for teaching sexual anatomy," "disclosing areas of sexual blocking," "for specific sexual problems [by being a normal partner]," "to demonstrate there is no physical cause for absence of libido," "to relieve frustration in a widow or divorcée who hasn't yet re-engaged in dating," "in mature patients flowing with nonconflicted [love] feelings," and "in healthy patients by mutual consent making the therapy go faster, deeper, and increases dreams."

There was significance ($p<.05$) between these two groups of responses. This was due to the proportionately larger number of surgeons ($N=6$) who favored the use of erotic behavior with patients as contrasted with general practitioners ($N=1$) so stating. In addition, ten psychiatrists, six obstetrician-gynecologists, and five internists gave responses favoring erotic behavior with patients.

A separate question asked for the actual number of patients involved with the physician in erotic behavior, specifically *excluding* intercourse. Of the responses, 89 percent ($N=277$) reported no such patient contact, while 11 percent ($N=33$) indicated affirmatively by specifying the number of patients so involved. Of those who responded affirmatively, 70 percent ($N=23$) reported that it occurred with fewer than five patients. Similar inquiry was made regarding the actual number of patients involved with the physician in erotic behavior, specifically *including* intercourse. Of these respondents, 89 percent ($N=263$) reported no such contact, while 11 percent ($N=33$) acknowledged such experiences. Of those who reported intercourse with patients, 79 percent ($N=26$) indicated that it involved fewer than five patients.

The four questions "Do you engage in erotic practices?" (table 3), "Would this include intercourse?" (table 3), "How many patients involved, excluding intercourse?" (table 4), and "How many patients including intercourse?" (table 4) served to delineate the incidence of erotic practices. A total of 59 physicians answered one or more of these four questions, while 33 respondents provided information for the last two questions. These data are presented in table 4. The distribution of responses was not statistically significant.

The results of these four questions would indicate that five to 13 percent of the total sample ($N=460$) engaged in

TABLE 4
Comparison of Erotic Behavior by Total Sample and by Specialty

Category	N	Any Kind of Erotic Behavior			Erotic Behavior Excluding Intercourse			Erotic Behavior Including Intercourse		
		Number of Respondents	Percentage of Specialty	Percentage of Total Sample	Number of Respondents	Percentage of Specialty	Percentage of Total Sample	Number of Respondents	Percentage of Specialty	Percentage of Total Sample
Total	460	59	—	12.8	33	—	7.2	33	—	7.2
P	114	12	10	2.6	6	5	1.3	6	5	1.3

GP	105	14	13	3.0	9	9	2.0	9	9	2.0

some kind of erotic behavior with their patients (tables 3 and 4). Similarly, the incidence of erotic behavior, specifically including sexual intercourse, was five to 7.2 percent (tables 3 and 4).

A final space on the questionnaire provided for additional comments; it elicited 124 responses, which were sorted into eight categories. General comments, one of the eight categories, comprised 47 percent (N=58) of these responses and included discussions of the problems that would result from erotic behavior, questions about methodology, and an urging for more teaching in medical schools of sexual matters and for special seminars on this subject for practitioners. Four respondents (three percent) acknowledged that they knew "such things [erotic behavior] go on." Nine (seven percent) stated that sexual behavior should be kept out of the office. Twelve (ten percent) stated that erotic behavior was symptomatic of a doctor's illness. Nine (seven percent) indicated that they did not know if erotic behavior was beneficial or not. Fifteen (12 percent) felt that such behavior destroyed the doctor-patient relationship. Five (four percent) indicated great anger that this study was undertaken, i.e., "proves psychiatrists are nuts," "an insult to even be asked," "you're sick." In contrast, 12 of the respondents' comments (ten percent) were of a congratulatory nature applauding the effort and encouraging continued study.

DISCUSSION

The questionnaire afforded respondents a unique and anonymous opportunity for the expression of participation in unusual practices, and the data are therefore more likely to be representative of such practices. Each specialty represented tended to have its own slightly different orientation regarding engaging in the treatment of sexual problems and beliefs and practices regarding both erotic and nonerotic behavior with patients.

Psychiatrists and obstetrician-gynecologists reported a much higher frequency of the treatment of sexual disorders in their practices and were also more wary of nonerotic physical contact than their colleagues, since they primarily believed that such behavior would be misunderstood. At the same time, it was the psychiatrist who most often explained why such contact might be beneficial in the treatment of a patient. Internists and general practitioners, on the other hand, indicated a belief in and practice of beneficial, nonerotic physical contact with their patients. While surgeons differed sharply from the other respondents in overall response rate and frequency of treating sexual problems, they were, nonetheless, more allied with psychiatrists and obstetrician-gynecologists regarding beliefs and practices of nonerotic physical contact.

The questions regarding actually engaging in any erotic behavior with patients, and in sexual intercourse specifically, indicated a lower incidence (five percent) than did those questions asking for a specific number of patients involved in any erotic behavior (13 percent) and in sexual intercourse specifically (7.2 percent). Possible explanations for this variance include: 1) these questions differed from the others by requiring that a specific number be given and 2) they appeared later in the questionnaire, apart from the patient management considerations per se. Further, physicians participating in this kind of activity with patients do so because they feel they have both a professional and a separate social relationship with these patients. Several respondents specifically gave this explanation on their questionnaires.

It was in the area of belief—not practice—that erotic contact may be beneficial that the surgeons differed from the other respondents (table 3). They constituted 26 percent (N=17) of the total sample of 19 percent (N=88) of physicians who believed that such behavior might be beneficial. Twenty percent of the psychiatrists (N=22) held this view.

It may be worthwhile to compare these responses (19 percent) by physicians with those of medical students, since the latter group represents an earlier phase in the professional career. Wagner (11) reported that 25 percent of the freshmen medical students surveyed felt that sexual intercourse with a patient could be appropriate under the "right circumstances" if the doctor was "genuine" and "authentic." These figures delineate a core of both physicians-in-training and physicians-in-practice, separated by years of age and years of medical practice experience, who are seriously asking, "Why not?" It is a question deserving of an answer and represents an important

challenge to medical teachers engaged in sex education. A greater understanding of the emotional parallel between the doctor-patient and parent-child relationships may provide such an answer. Of particular interest in this regard is Woodbury and Schwartz's study of parent-child incest (12), which indicated an incidence similar to that of the doctor-patient erotic contact reported here.

Answers to Questions of the Month

Page 1070. Question 1:C; Question 2:E.

Psychiatry in Shanghai, China: Observations in 1973

BY DAVID N. RATNAVALE, M.D.

At the invitation of the Chinese Ministry of Health, the author visited China earlier this year. He describes the structure and organization of the Shanghai Psychiatric Institute, a therapeutic community in which the staff and patients work together in a classless social organization, which is part of a medical system that blends the modern and the ancient traditional medical practices. The author presents brief general information on acupuncture and describes its use in psychiatry, but stresses the preeminence of group activities in the therapy of mental illness.

THE CLINICAL MANAGEMENT and care provided to persons suffering from psychiatric illness cannot be described in isolation from the cultural, social, economic, and political milieu from which they spring. Hence, the interpretation of modern trends in a land as ancient and as immense as China is no ordinary task. The problem is further compounded by our scientific requirement of perceiving change through Chinese senses while maintaining an objective investigatory posture.

The people of China, when faced with psychological issues, are reputed to have ready mental access to a vast compendium of "old Chinese sayings." This may simply give them time to ponder before reacting, but it reveals plainly their reverence for the ancient and their readiness to connect the past and the present.

We are now seeing the consequence of Chairman Mao Tse-tung's call during the Great Leap Forward in 1958: "Chinese medicine and pharmacology are a great treasure house. Efforts should be made to explore them and raise them to a higher standard." He has given impetus to the study of ancient Chinese medicine and modern medical science contemporaneously; through the vigorous pursuit of this national policy he has substantially reoriented the entire system of medical practice and teaching in China. Psychiatrists and mental health workers in China tell us that the developments in their psychiatric services parallel the growth observable in all other spheres of human activity and thought since the "liberation" of 1949.

I was invited by the Ministry of Health and the staff of the Shanghai Psychiatric Institute to study current psychiatric practice in China and to share my research experience in Sri Lanka (formerly Ceylon), where I had investigated the difficulties inherent in any attempt to blend the ancient indigenous (ayurvedic) medical system with Western medicine. This paper presents a description of a hospital in Shanghai, one of the world's largest cities, in the Kiangsu Province of the People's Republic of China. I shall attempt to identify modern trends in psychiatry and the therapeutic modalities in use. Special attention will be paid to acupuncture in psychiatry and therapeutic group processes.

At the time this paper was written, Dr. Ratnavale was a senior psychotherapist at Chestnut Lodge, Rockville, Md. He is now Associate Professor of Psychiatry, Eastern Virginia Medical School, 721 Fairfax Ave., Norfolk, Va. 23507.

SHANGHAI PSYCHIATRIC INSTITUTE

The Shanghai Psychiatric Institute, constructed in 1958, is a large complex of modern concrete buildings situated in a surburban section of Shanghai. The 1,000-bed hospital and the specialized departments that serve it cover half the total area of the premises (40,000 square meters), which itself is enclosed by a cinnamon-colored wall three meters high. Directly across the road—Chin Chi Road—lies the impressive Lon Hwa General and Teaching Hospital.

As one enters the imposing gates of the Shanghai Psychiatric Institute, one's gaze is met by a tall rectangular slab of cement bearing a quotation of Chairman Mao Tse-tung about freedom. The buildings of the institute surround a spacious garden-like courtyard where patients are seen at play; it is tastefully landscaped with flowering and evergreen trees.

The hospital is divided into 13 airy and plainly furnished units with rooms that sleep eight to 16 patients. The patients have the responsibility for maintaining their quarters but are assisted in this function by the nurses and health workers. There are a few single rooms but these are rarely used, since the isolation of patients is strongly discouraged. On one wall of every unit is painted an appropriate quotation from Chairman Mao, e.g., "Help one another; care for one other; love one another."

The Psychiatric Institute is served by a staff of 556 persons. Fifteen administrators, four of whom are psychiatrists, under the chairman of the revolutionary committee of the hospital, are responsible for managing the institution. Dr. Yen Ho-Chun, a psychiatrist, is the medical director. His assistant, Dr. Shu Sun-Ha, is also the vice-chairman and has just completed two years of specialized instruction at a famous center for Chinese traditional medicine. Of the 61 psychiatrists, 11 are women. All have received training in both modern Western medicine and traditional Chinese medicine.

At any given time as many as a third of the staff psychiatrists are away in rural areas serving with other specialists on mobile medical teams for as long as six to 12 months. There they are engaged in treating patients, instructing commune and barefoot doctors (*chú chiao*—"a peasant who has had basic medical training and gives treatment without leaving productive work" [1]), and disseminating information on mental health. Their rural encounter is also considered to be a learning experience.

A distinctive feature of the working staff of the hospital, which includes 218 nurses, is the absence of any insignia of rank. Indeed, my overall impression was that staff members were under less stress than their fellows in other lands and I was struck by the ease of conversation among professional, paraprofessional, and patient.

The Shanghai Psychiatric Institute and similar institutions provide treatment facilities for the whole society; it is asserted that, in the preliberation period when adequate health care was available only to the privileged classes, "hospitals did not satisfy the needs of the people." The patients are now receiving the benefits of both the traditional Chinese and the modern Western medical systems and treatment is provided for all types of mental illness. The outpatient clinic is reported to receive as many as 400 patients a day, the majority suffering from neurotic and psychosomatic conditions. A small percentage of patients with epilepsy are also seen for checkups or renewal of medication. On the average, hospitalization lasts for ten to 12 weeks and families generally visit patients twice a week. There is no charge for therapy, but a small payment is sometimes levied for food.

There is no separate staff category that corresponds to our social workers. The functions of social work are absorbed by the working staff, who maintain steady contact with families and with members of the patients' working units. Every patient is certain that his job will be waiting for him when he returns to work.

The inpatients range in age from 20 to 35. The incidence of psychiatric disorders below the age of 15 is said to be very low. Indeed, the absence of aged, regressed, or agitated patients is also striking. Over half the patient population suffers illness of psychotic proportions, chiefly schizophrenic syndromes. The psychiatrists are unanimous in their claim that the incidence of depressive syndromes (*yu yiu-tsen*), postpartum psychosis, and suicide is significantly low. They also note the rarity of senile psychoses—an observation recorded by Tsung-Yi Lin in another Chinese community (2).

They also asserted that chronic alcoholism, opiate addiction, and drug abuse in general had been eliminated, and I concur with the group of American physicians who visited China in 1971 that "not a single instance of drunkenness was observed day or night in our travels in the cities and countryside" (3). Our Chinese colleagues attribute their success partly to widespread educational campaigns and partly to the efficient halting of illicit production. Lowinger (4) considered "the changed ideology of the young people . . . the changes in outlook, which included a redefinition of the nation and its youth, of their worth and role" to be a major force. Indeed, the eradication of the poppy fields in a land that is 80 percent "countryside" and the recultivation of these fields with food crops indicates the size of the task and the efficiency of the programs.

The newer developments within the Shanghai Psychiatric Institute are identified with parallel changes in the nation as a whole; they indicate that a shift in the attitude toward mental patients and their care followed in the wake of the "great proletarian revolution" under Chairman Mao's leadership. He is quoted frequently as a source of guidance and inspiration and his sayings are conspicuously displayed in all public places. He is seen as a true advocate of the classless society, in which all hospital workers and all patients belong to one socioeconomic category, and all remember his exhortation to approach patients "with wholeheartedness," "paying attention to environment and past beliefs." He sponsored the revival of ancient and traditional medicine (including acupuncture) and the establishment of equal status for modern Western-oriented physicians (*si-i*), barefoot doctors (*chú-chiao*), and traditional healers (*zjung-i*).

The physicians and health workers at the Psychiatric Institute emphasized the point that, in line with the concept of a people's republic, the hospital is perceived as a people's hospital, and they were generally inclined to view each ward or hospital unit as a family.

TREATMENT: METHODS AND PHILOSOPHY

The preeminent therapeutic emphasis appears to be related to the reestablishment of a "sense of group" or "sense of belonging." The group therapeutic activities include ideological education, play, singing, reading, and "heart-to-heart talks." One can add "group acupuncture" to this list since acupuncture is now administered to more than one patient simultaneously. Chemotherapy, herbal medicine, and acupuncture comprise the nonpsychological approaches. Electroconvulsive therapy and insulin shock treatment have been discontinued.

Chemotherapy

The standard Western psychopharmacological products (e.g., tricyclic antidepressants and phenothiazines) are used, along with herbal preparations. In general, the dosages are smaller than those prescribed in the West; 250 mg. of chlorpromazine per day is considered to be a high dose. It is suggested that the concurrent administration of herbal medicines reduces the need for higher dosages. The Psychiatric Institute maintains a large herb pharmacy that dispenses pills and decoctions manufactured from medicinal roots, bark, and leaves.

Acupuncture

Acupuncture appeared in Central Asia as early as the Neolithic period and its application has been passed down to us through a few records. An extensive exposition is found in the *Huang-ti Nei Ching Su Wen* [*The*

Yellow Emperor's Classic of Internal Medicine] (5), whose composition is placed by some authorities at 2697 B.C. and by others at the third to fifth century B.C. (6). A textbook, it takes the form of a dialogue or "familiar conversations" between Huang-ti the Emperor and his minister-physician Ch'i Po. Students of Chinese medicine look to the *Nei Ching* not only to read medical history, but also to understand its development and current usage.

Acupuncture consists of the insertion of needles into particular points on the body that lie along 12 channels or *ching* (*ching lo* theory). These *ching* are said to be deeply set and not in direct communication with the blood vessels but to emerge to the surface at 365 or more places, presenting the points for needling. The anatomical locations of these *ching* have yet to be defined. Acupuncture, which is widely practiced in China, involves an understanding of the principles of *yin* and *yang*, maintaining a balance between *ch'i* (air) and *shiueh* (blood), and "needling," which establishes equilibrium by removing stagnation and neutralizing excesses.

The use of acupuncture in psychiatry and anesthesia is of relatively recent origin. Though its use in psychiatry has not been adequately reported in the literature, despite its regular use in Chinese mental hospitals, acupuncture anesthesia has won considerable publicity and is extensively employed in China (by conservative estimate it has been used in more than 400,000 operations since 1968) with a 90 percent reported success rate.

The Melzack-Wall hypothesis (7) offered some hope of a neurophysiological explanation for acupuncture anesthesia, but the answer remains unsettled. This hypothesis holds that perception of pain involves a "gate control" system, primarily located in the substantia gelatinosa of the spinal cord, and that effective closure of this "gate" blocks pain from reaching the higher centers. Man and Chen (8) postulated that there is a second gate in the thalamus, while others have summarily dismissed the phenomenon as something that makes "no sense anatomically" or that it is due simply to the effect of distraction and hysteria. Even serious students have been vocal about the "power of suggestion," but they are hard pressed to explain what they mean. Cooperative exploration by psychologists, psychiatrists, and neurophysiologists is surely called for. Huard and Wong (6), reporting on acupuncture in psychiatry, noted that "in psychiatry the effect of acupuncture is nonexistent, and hysterical and coxalgic patients have been seen to resist the needles but not the electric shock" (p. 215). Sidel (9) has reported the use of acupuncture in treating schizophrenia, excitement, catatonia, and depression.

I observed the administration of acupuncture to patients individually and in groups at the Shanghai Psychiatric Institute, where acupuncture has been in use since 1966 and is now standard treatment. Psychotic and neurotic patients are given acupuncture along with other types of treatment. It is considered particularly helpful in treating syndromes characterized by excitement, anxiety, apathy, catatonic stupor, and depression. Points on the limbs and trunk have been identified for needling in psychiatric conditions; they lie along the standard *ching*, but why these points have been selected over others has still to be explained. Future research must satisfy this question and also establish the specific value of this form of treatment.

Eleven points reported to be specific for psychiatric illness are: *ho ku*, a *yang ching* on the extensor aspect of the hand in the muscle belly of the first dorsal interosseous muscle; *nei kuan*, a point on the flexor aspect of the forearm one inch from the wrist crease; *lau kong*, in the center of the palm; *shiao shang*, a *ying ching* on the outer aspect of the nail bed of the thumb; *tsu san li*, a point one inch below and behind the head of the fibula; *tai shung*, on a line between the first and second toe, two fingerbreadths above the web; *yung chuwan*, on the sole of the foot at the junction of the anterior and middle third; *yi fong*, on the posterior aspect of the ear lobe; *tin kong*, immediately anterior to the tragus of the ear; *bei wei*, on the center of the scalp; and *tai yang*, at the temple.

During acupuncture the patient usually complains of a mild local "soreness," "distension," or "tightness." Manual twirling of the needle is still practiced but more commonly a current of four to six volts is passed to the implanted needle via a portable regulator box no bigger than a small transistor radio. The box, with several terminals, allows for treating more than one patient (as many as six) at a time and requires only one therapist. Each treatment lasts 20 to 30 minutes and is administered twice daily, daily, or three times a week. A positive response (essentially the reduction of symptoms) is usually noticed after two weeks of treatment, but the course generally lasts from five to six weeks. If no improvement is noted in three weeks the method is discontinued.

The doctors at the Shanghai Psychiatric Institute implied that acupuncture has replaced ECT in their hospitals but they do not, at this stage, venture any definite explanation of its action. They list its advantages over ECT and note primarily its safety, simplicity, and availability and the absence of such side effects as memory impairment. It must be emphasized that doctors and scientists in China make no pretense of fully understanding the action and effect of acupuncture and that active research is going on in this area.

Therapeutic Group Processes

Group play at the Shanghai Psychiatric Institute chiefly involves uncomplicated noncompetitive games. Groups of patients are seen lobbing a basketball to one another in a game that resembles "catch." Another game consists of tossing a rubber ball or shuttlecock to a partner with a wooden paddle. In table tennis, however, a little of the competitive spirit is evidenced.

In group singing patients and nurses stand around a pianist and violin player and sing animated folk songs or songs of victory that have a somewhat martial flavor and that deal with liberation and freedom.

In group reading patients or health workers take turns reading simple literary works, news reports, or children's books.

"Heart-to-heart talks" amount to informal chats in small groups or individually with a psychiatrist or nurse.

Ideological Education

By far the most emphasized therapeutic group activity is ideological education. It is given to all patients at some period of their hospital life. A newly admitted acutely disturbed or confused patient does not participate in this mental exercise until the ward psychiatrist, nurse-instructor, and patient group acknowledge his ability to become involved.

This method is aimed at "mobilizing the patient's initiative" through discussions, questions, and the examination of such famous works as the teachings of Chairman Mao. The subject matter is concerned with objectivity, freedom, openness, equality, and caring for one another and represents the basic material for ideological education. Learning and discussing the teachings of Chairman Mao, it should be noted, is a popular and serious activity in all spheres of life in China; reading, studying, and debating his works is considered to be a highly salutary pursuit. It is understandable that this would be a part of hospital life.

In these sessions, asking questions and repeating them until they are satisfactorily clarified is greatly encouraged. There are thus no "stupid questions," only comrades who cannot adequately explain their answers. For example, a group may be engaged in the study of Mao Tse-tung's writing on "Where do correct ideas come from?" or "Can bad things be turned into good things?" This would be the basic material for exploring the ideas and feelings of the patients. In one such discussion, the nurse-instructor (the group leader) expressed the view that, in interacting with patients, a group leader "must not be critical, but instead willing to explore the conflict that led to the patient's puzzlement or false ideas; that an atmosphere of trust must be created and engendered; that investigations and explorations should be wholehearted and intensive."

Case Report

The following report was related to me by a psychiatrist at the Shanghai Psychiatric Institute[1]:

A woman nearing the age of 50 (the usual retirement age) was informed by her working unit that she was going to be retired. She had a "false thought" that she was being expelled and wondered whether she was to be dismissed because her ability and performance were poorer than those of the other workers. She got the idea that if she worked hard she might be offered the opportunity of working two shifts instead of one. She was, of course, actually ill. In addition, she had insomnia and loss of appetite. At the institute her treatment consisted of chemotherapy, acupuncture, and group activities.

In her group, she was urged to compare the past and the present, the time before liberation and the present time. She was reminded that in the past the old workers, the aged workers, were "kicked out by the capitalists" and that it was very difficult for them to obtain any pension or other support. Her "actual" current situation and the new labor regulations that provide certain guarantees were explained to her. She was helped to recognize that there was glory in the work she had already done and that she could retire with the feeling that her career was one that brought glory to herself and to her country. She was helped to see that her thoughts were distorted and therefore wrong. She enjoyed and benefited greatly from her group experience.

Follow-up of her case was carried out at the outpatient clinic; weeks after her discharge the unit wrote to her and she replied with news of her improved state. In cases of this kind, the "visiting team" would go to the patient's home or working place to check on her progress and to help "consolidate the efficiency" of her improved state. Her treatment was therefore a combination of chemotherapy, acupuncture, and group therapy. Follow-up aided in consolidating her gains and facilitating the development of a new relationship between her and her fellow workers.

We are frequently disappointed when our theoretical conceptualizations fail to explain the action or results of techniques unfamiliar to us. The language is the same but the dialects are different, a situation that creates no less misunderstanding than has existed between so-called organicists and those considered psychodynamically oriented.

How are we to understand the clinical example cited or the statement that "ideological education is offered in a way that helps to integrate and reorganize a patient's thinking"? Is it enough to accept therapeutic efficacy simply in terms of realigning illogical thought through a dialectic process (defined as the art or practice of examining opinions or ideas logically, often by a method of question and answer so as to determine their validity), or can we safely assume that other psychological events are taking place concurrently?

We are faced with the task of translating traditional Western concepts concerned with such things as the mother-child relationship, ego development, psychosexual phases, psychic trauma, and transference to the state of affairs that prevails in China and of opening our minds to new ideas. In such a pursuit it would be wise to guard against too hasty a presumption that our Chinese colleagues organize these concepts along similar lines but within a framework that we do not as yet understand. They are willing to share their clinical experience and for this privilege we are obliged to study *with them* the intricacies of the methods they employ. We are called upon to face simple questions related to causation and curability. In a field that has no universal criteria for cure, we must at least be content to accept as a primary consideration a patient's capacity to return to his work and his home life.

If we begin to scrutinize one of the primary psychological therapies practiced at the Shanghai Psychiatric Institute, with an inclination to view it as a form of group therapy, it would be perfectly valid to ask why it receives their main emphasis, what makes it an effective modality, and how it works.

In the West, and especially in the United States, group therapy as a psychotherapeutic method has almost lost the stamp of science. Its exponents vary from psycho-

[1] When I asked whether this patient's case would fit in the category of depressive illness, I was informed that she had received a diagnosis of "involutional melancholia."

analysts to nudists, and it has come to mean (in the public eye) any type of group activity that ameliorates psychic tensions and that facilitates improved interpersonal relationships. Regrettably, there is little consensus regarding the indications for group therapy, although there is general agreement that people who are deprived of adequate group experiences or who are unduly uncomfortable in groups can benefit from such treatment. We also know that cultural and social factors—one's concept of family life, of independence and autonomy, of intrafamily loves and jealousies—all influence attitudes toward one's self and one's fellows.

Reduced to its simplest meaning, group therapy aims at the evolution of a sense of group or the redevelopment of that sense, once known but abandoned. Within this simple context, it might be profitable to consider the meanings of "group sense" to a person in Chinese society today and its value and significance in group treatments in Chinese mental institutions.

The attitude of Westerners toward China has fluctuated considerably during recent centuries and has significantly influenced Western perceptions of the Chinese character. Anthropologists and social scientists speak of the Chinese need to "save face" and their "inscrutability." Western LaBarre (10), writing in 1946, noted that "the Chinese are not militaristic . . . not imperialistic . . . non-mercantile . . . and not essentially an urban people." Weakland (11), in "Orality in Chinese Conceptions of Male Genital Sexuality," discussed their "oral thinking." Hsein Rin (12) noted the marked emphasis on orality in the Chinese, giving as evidence "the frequent and prolonged breast feeding of babies and the prominent and almost exclusive role of mothers in bringing up children." Tsung-Yi Lin (2) observed that "the threshold of Chinese families in regard to abnormal behavior is rather high." Muensterberger (13), in a study of the character of the southern Chinese, wrote that "those who know report that, although the Chinese woman suffers under many restrictions, she plays a more influential role within her family than does the man."

In general, students of Sinitic studies agree that, however alien the surroundings, the fundamental and centrally organizing factor in Chinese social life is the family. That this appears to be true of modern China is hard to dispute, and a discussion of the persistence of this characteristic in the face of radical alterations in role functions and expectations in the present-day Chinese family group is a worthwhile project.

ASPECTS OF GROUP CONSCIOUSNESS

The meaning of the group may well be somehow different in China, but there is evidence to suggest that the group has a highly therapeutic meaning. Interpreting national policy and its influence upon Chinese society is beyond the scope of this paper, but reference must be made to current developments within the nation that appear to significantly enhance group consciousness throughout life. At least four intimately related areas deserve our close attention: 1) the reverence toward children in modern China, 2) the liberation of women, 3) a heightened awareness of the oppressed minorities, and 4) the popularity of "speaking bitterness." Inherent in these phenomena is a recollection of how things used to be and an affirmation of the positive changes that have been made.

Reverence for Children

Despite historical references to poverty-stricken eras when parents were driven to extremes, the Chinese love of children is taken for granted. This basic attitude is being augmented by present-day leadership. Mao Tse-tung has said: "The world is yours, as well as ours, but in the last analysis it is yours. You young people, full of vigor and vitality, are in the bloom of your life, like the sun at eight or nine in the morning. Our hope is placed on you. The world belongs to you. China's future belongs to you."

From very early in an infant's life, as early as 56 days old, he might be placed, like 90 percent of his peers, in the nursing room of the factory where his mother works. She will come to feed him at least twice each day, but during the rest of the working day he is in the care of several "aunties." These aunties, or auxiliary mothers, are selected from among the workers and chosen for their patience, warmth, and heightened sense of responsibility. Thus, quite early a mother begins to rely on other people to assist her in rearing her babies, and the child comes to recognize that he is a member of a group. Indeed, the children feed together, play together, and after breakfast sit on individual potties and have their bowel movements together.

News about new schools and about developments in education is widely disseminated. Under the title "More Nurseries and Kindergartens in Tienstin," the *Chinese Medical Journal* (14) reported: "In addition to singing and dancing lessons, the children learn to tend vegetable gardens and raise chickens and rabbits in order to inculcate in them the love of labor," and under the title "Better Health for Tibetans": "Nurseries and kindergartens are staffed, in the main, by young women who have received special training in child psychology, health protection, and nutrition. Research work is being conducted to improve the care and education of pre-school age children. Meetings of child care workers, for exchanging experiences, are held regularly."

Women's Liberation

It is generally believed that, until recently, women held an inferior position in China and were the voiceless, faceless, footbound servants of their masters, gaining a modicum of status only upon becoming mothers-in-law. New marriage laws, social changes, and raised expectations have altered their traditional postures so that now they kowtow to no one, enjoy equal rights, and receive equal pay for equal work. R. Sidel's observations (15) lend credence to these changes, noting also that basic attitudes toward motherhood remain stable.

Oppressed Groups of Past Days

It is well known that in bygone times peasants and minority nationalities, especially in remote regions, were at the mercy of warlords who plundered their produce and held them in fear and submission. These groups are now enjoying the limelight in a conscious, deliberate manner. The theater, opera, and radio consistently depict their earlier predicament and compare the past with the present. It would appear that the term "minority" is frequently equated with "underprivileged," in a way that expresses the earlier status of the peasant classes (who, though numerically in the majority, were the minority in a social and economic sense).

Speaking Bitterness

"Speaking bitterness" refers to a phenomenon that became very popular and was greatly encouraged after the liberation. Through "speak bitterness" meetings, an acceptable forum was created for people to describe their past hardships in a dramatically cathartic fashion. It served to purge one's impacted resentments and, through identificatory processes, the bitter feelings of their hearers as well. It served also to identify the present politicosocial system as one that rescues and nurtures, but apparently it did not stop there. Rather than foster a helpless dependency, the will of the individual and the group was bolstered into recognizing that only through their group consciousness, vigilance, and hard work could the present gains be protected and sustained.

Only four areas have been portrayed; presumably there are more. They have the quality of novelty and whet one's curiosity. Yet, they sound like old ideas or just ordinary sentiments. They seem to remind us that children have always been cherished—and needed it; that women invariably exerted profound psychological strengths—and needed to; that the oppressed and small at all times found an advocate; and, last but not least, that people have always complained.

I recognize the difficulties inherent in the interpretation of unfamiliar methods and ideas. I would caution against hasty generalizations and urge a deeper study of the topics discussed in this paper.

ACKNOWLEDGMENTS

I wish to thank my Chinese hosts, my colleagues at the Shanghai Psychiatric Clinic, and their patients for their trust and generosity. Without their help and the unhurried assistance of Dr. Yu Lu-yi and both Mr. Chiang and Mrs. Wu Sheu Cheng of Shanghai's Municipal Bureau of Public Health this work would not have been possible.

Evolving Behavior in the Clinical and Experimental Amphetamine (Model) Psychosis

BY EVERETT H. ELLINWOOD, JR., M.D., ABRAHAM SUDILOVSKY, M.D., AND LINDA M. NELSON

A parallel is drawn between several behavioral constellations observed in the evolution of the human amphetamine psychosis and the motor-postural-attitudinal manifestations induced in animals by chronic amphetamine intoxication. On the basis of the results reported, a triple-layered model of psychosis is suggested and the roles played by participating neurotransmitters and mechanisms are further elaborated.

IN A CLINICAL SETTING, the amphetamine psychosis develops over a period of time as the user gradually increases his intake of amphetamine to amounts ranging from 150 to 2000 mg. per day. Although the paranoid psychotic state evolves gradually as a result of this chronic abuse, the patient is seldom seen by a physician until the process is far advanced. By this time he presents a fairly distinct syndrome, with delusions of persecution, ideas of reference, visual and auditory hallucinations, changes in body image, hyperactivity, agitation, and panic.

In previous studies we have asked whether there are behaviors that precede the last stage and may, in fact, be related to the development of the paranoid schizophrenic-like picture. More specifically, we have been interested in the anlagen of the behaviors that evolve over time since several of the antecedent behaviors we have observed in human chronic amphetamine abusers present fairly distinct constellations or clusters (1, 2).

One of these constellations involves an intense feeling of curiosity, often manifested by repetitious, stereotyped examining, searching, and sorting behaviors. This repetitious activity has been variously called "punding" (3), "hung-up activity" (4), "obsessive-compulsive tendencies" (1, 5), and "knick-knacking" (by inhabitants of the Haight-Ashbury scene). Its characteristic feature is engagement in tasks that primarily involve small bits or minutiae and a marked enhancement of perceptual acuity directed toward these minute objects. At times there are perceptuo-motor compulsions, manifested as repetitious stringing of beads or as acts of arranging, sorting, and lining up pebbles, rocks, or other small objects (2). Most of the so-called "speed art" is replete with complicated syntheses of a multitude of minute details, often depicting universal themes or mandalas. Speed users are frequently observed taking apart such objects as television sets, watches, radios, and phonographs. Subsequently, the parts may be analyzed, arranged, sorted, filed, and cataloged and, rarely, put back together (2). Many patients report a sense of satisfaction associated with this compulsive-like conduct.

Perhaps the best-known example of searching and examining behavior is that of Sherlock Holmes, whose cocaine habit was described by Dr. Watson:

> Finally he thrust the sharp point home, pressed down the tiny piston, and sank back into the velvet-lined arm-chair with a long sigh of satisfaction. Three times a day for many months I had witnessed this performance. . . .
>
> "It is cocaine," he [Holmes] said, "a seven-per-cent solution. . . . I suppose that its influence is physically a bad one. I find it, however, so transcendently stimulating and clarifying to the mind that its secondary action is a matter of small moment. . . .
>
> "My mind," he said, "rebels at stagnation. Give me problems, give me work, give me the most abstruse cryptogram, or the most intricate analysis, and I am in my own proper atmosphere. I can dispense then with artificial stimulants. But I abhor the dull routine of existence. I crave for mental exaltation. That is why I have chosen my own particular profession, or rather created it, for I am the only one in the world. . . .
>
> "To the trained eye there is as much difference between the black ash of a Trichinopoly and the white fluff of a bird's-eye as there is between a cabbage and a potato."
>
> "You have an extraordinary genius for minutiae," I [Watson] remarked (6, pp. 610–612).

Holmes's description of his "grooving on" puzzles and cryptograms and his penchant for magnificent synthesis of details to solve a given case are quite analogous to the amphetamine addict's intense curiosity and preoccupation with minutiae. Even at a low point in the drug-use cycle, these persons will seek out stimulating mechanical or intellectual puzzles. This compulsion for analysis is widely recognized in the "speed scene."

Amphetamine addicts frequently state that the early scanning, prying, probing behaviors subsequently evolve into a pleasurable sense of "suspiciousness" in the origi-

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

nal meaning of the word—that is, looking beneath the surface for the truth or meaning (literally, "to look from below"). They describe looking for meaningful details or relationships between details.

Another progressive symptom noted by these patients is increased thinking about "meanings and essences." Insights are frequently received as significant major revelations, or "eureka experiences." For example, one patient stated, "I put things together from the past and present. Now I think I know what is going to happen to this world." These sudden emotional insights and the compulsion to analyze a variety of details to find meaning and explanation were common to both philosophical and delusional concerns (2).

Later in the course of amphetamine addiction, the direction of the inquisitive behavior is reversed and the addict feels that other people are probing—watching and spying on him. At this time the previously pleasant suspiciousness takes a more paranoid form, leading eventually to fear or even agitation, hyperreactivity, and panic. The addict may then begin to misinterpret stimuli and often to have illusions and hallucinations. Thus it might be said that the initial periods of pleasurable curiosity and suspiciousness set the stage for the eventual paranoid reaction.

EXPERIMENTAL STUDIES IN ANIMALS

In the experimental laboratory, chronically intoxicated animals manifest evolving clusters of behavior comparable to those just described in amphetamine addicts (7). In our experiments we have used the operational approach that the laboratory observations have heuristic value in elucidating the nature of the amphetamine psychotic state itself; we are summarizing in this paper the animal behaviors that are analogous to those seen in human amphetamine abusers. The details of these experiments, performed on rats, cats, and rhesus monkeys, have been reported elsewhere (7–11).

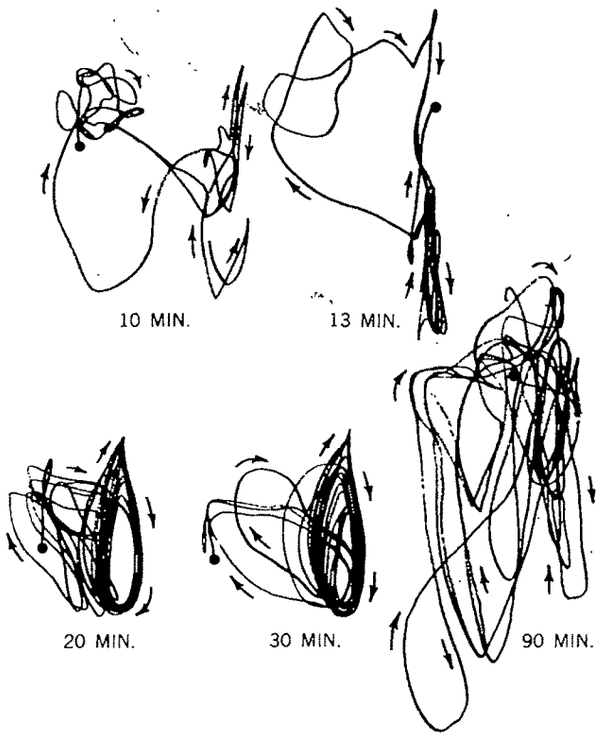
Stereotypies

Stereotyped movements are the hallmark of both acute and chronic amphetamine intoxication. They may consist of a single activity performed continuously or a sequence of a few activities that dominate behavior (8, 12, 13). Usually these stereotypies appear nondistractible and "driven" (performed in a rapid, repetitious manner). They most often evolve from motor components of investigative behavior. In both our acute and chronic intoxication studies across species, the one common denominator of amphetamine-induced stereotyped movements was that they were composed of patterns of searching and examining (10). The motor components, at least, of these patterns are present in the stereotypies of all species studied.

In macrosmatic animals, such as the rat, the primary stereotyped mode is that of sniffing, although biting and licking are also noted. As one moves up the phylogenetic scale to cats, the sniffing movements remain, but head movements associated with looking are also prominent. In primates a new dimension, eye-hand examination patterns, is added. These hand movements are quite specific and consist primarily of forefinger probing, pincer-like grasping, picking, palm-clasping, and hand-examining. The underlying postural-motor components are similar in all of these motor activities. An individual motor component of the searching-examining patterns can be integrated into several stereotypies and may be directed either toward external objects or toward the animal's own body (as in patterns of grooming).

Over time, the stereotyped patterns become more repetitious and more constricted. Figure 1 illustrates the gradual constriction of a cat's head and neck movements that orient the head for visual regard. Over a period of two weeks, the orienting background movements often tend to drop out, leaving a small, pecking-like movement of the head in an extremely constricted pattern, as if the cat were sniffing at a small crumb or tiny morsel of food.

Attitudes and Postures



One of the most characteristic series of changes observed in cats during the period of chronic intoxication occurred in the animal's attitude.[1] The most frequent characteristic of early amphetamine intoxication was an abnormal investigative attitude—operationally defined as actively reaching out to or approaching restricted elements of the environment, with an excessively compulsive appearance. The evolution of the stereotyped motor behavior was intimately related to the abnormal investigative attitude (figure 2) and at times this attitude would persist in a given animal even after the motor stereotypy had ceased.

Another distinctive attitude, which appeared primarily in the later days of the intoxication cycle, was the reactive attitude—characterized by sudden, disproportionate startle reactions with a jumpy, agitated quality. This abnormal reactiveness was heralded by an increase in the speed and suddenness of movements and was later accompanied by a general increase in activity and agitation. At times the animals' movements were suggestive of akathisia and dyskinesia. In the end stages of the chronic intoxication cycle, even though the animal might be in a frozen posture, sudden orienting movements toward a real or "hallucinated" stimulus were often observed. Many animals appeared to be increasingly aware of minor stimuli in their environment and acutely apprehensive about it.

This intense hypersensitivity to the environment was a dramatic reversal of the complete disregard for transient environmental stimuli that characterized the abnormal investigative attitude. Although in the end stage much of the reactiveness appeared to be oriented toward "internal" cues, there was no question that minor external stimuli often overwhelmingly impinged on the animal in a way that triggered a fearful, overreactive orienting response. A slight, remote sound in the laboratory, for ex-

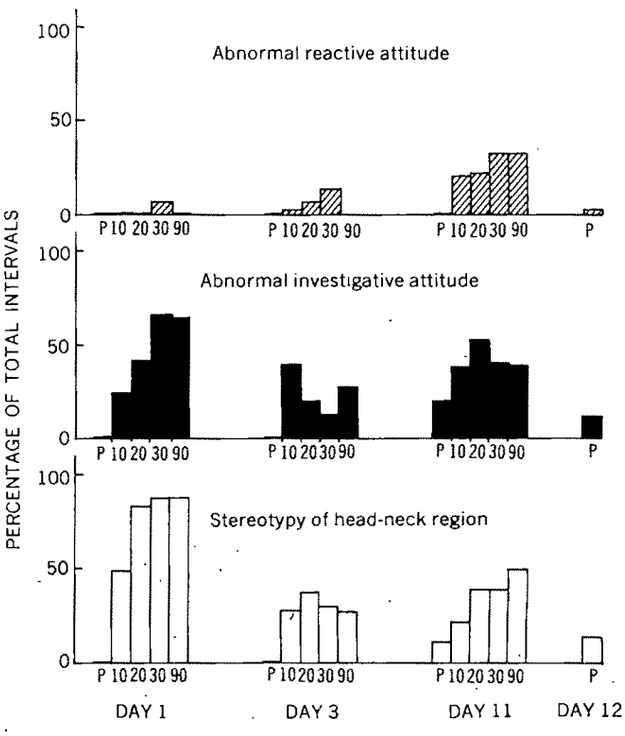
[1] In our studies "attitude" is operationally defined as body posture and activity in relation to the environment. This includes the animal's regard and reaction not only to his surroundings but also to his own body.

FIGURE 1
*Progress of the Tip of a Cat's Nose, Traced from a Slow-Motion Videotape**

*Each tracing represents 30 seconds of activity at the indicated time after the injection of amphetamine on day 1.

ample, might cause a violent turning of the head or jumping by a cat that ignored gross movements within its immediate field of vision. Or a glimpse of its own image on the shiny wall of the cage would cause a cat to jump back in apparent panic. Not infrequently a cat would jump back and turn vigorously to one side in response to a nonexistent (apparently hallucinatory) stimulus.

In the early days of intoxication, the persistent restrictiveness and directedness of the animals' behavior were reflected in their "postural-attitudinal" set as well as in their stereotyped movements. As intoxication progressed, however, there was increasing dissociation between the animals' underlying postural base and the superimposed movements and attitude. Toward the end of the intoxication period, a given animal might change his activity while maintaining the same posture—with the result that the behavior-posture relationship appeared dysjunctive and bizarre.



The last stage of intoxication was often characterized by akathisia-like repositioning and stepping movements that had the same agitated starting-and-stopping quality frequently noted in psychiatric patients with more chronic extrapyramidal manifestations induced by neuroleptic drugs. Toward the last day of the two-week study period many animals showed transient or adventitious movements that appeared to have little or no relationship to the main vector of behavior and that at times appeared incongruent to the overall behavioral configuration. The composite picture was one of hyperkinesia, in which the gradual breakdown of organized behavior accompanied an abnormally aroused and often fearful state.

DISCUSSION

Similarities Between Experimental and Clinical Amphetamine Intoxication

We have attempted to relate the progressive stages of chronic amphetamine intoxication in animals to the evolving stages of behavioral psychopathology observed in human amphetamine abusers. Because of their cognitive-perceptual nature, the symptoms most eminently related to the evolving paranoid psychosis are difficult to correlate directly with behavioral manifestations in lower animals. Remarkable similarities do exist, however, and in general it appears that the evolution of behavior in animal models is in many ways analogous to that noted in human patients. Table 1 presents our triple-layered

FIGURE 2
*Relationship Between Attitudes and Stereotypy During the Course of Amphetamine Intoxication**

*Each bar represents the occurrence of the behavior in a three-minute observation period on the indicated day during the preinjection period (P) or at ten, 20, 30, or 90 minutes after injection.

TABLE 1

Triple-Layered Analysis of Chronic Amphetamine Intoxication as a Model of Functional Paranoid Psychosis

Category	Early Stages	Intermediate Stages	End Stages
Functional paranoid psychosis	Paranoid tendencies		Paranoid psychosis
Human model psychosis (chronic amphetamine intoxication)	Curiosity: repetitious examining, searching, sorting behavior	Sustained pleasurable suspiciousness: looking for meanings, minutiae	Ideas of reference; persecutory delusions and hallucinations: fearful, panic-stricken, agitated, overreactive
Animal model psychosis (chronic amphetamine intoxication)	Abnormal investigatory attitude with repetitious activity	Restricted repetitious activity	Reactive attitude

model, in which amphetamine psychosis serves as a model of functional paranoid psychosis, and chronic intoxication studies in animals serve as a behavioral model of amphetamine psychosis.

The activities of many amphetamine abusers demonstrate a remarkable resemblance to patterns of examining behavior seen in animals. For example, amphetamine-induced repetitive "grooming behavior" in human addicts is not unlike that noted in rhesus monkeys. Usually it is manifested as incessant examining, rubbing, and picking (using the forefinger probe and pincer grasp), which often result in raw blemishes and in scars. Individual patients observed through a one-way screen sometimes spend hours examining and probing visually accessible parts of the body (9).

These same behaviors demonstrate the importance of the time dimension in the formation of delusions through the gradual organization of behavior, thought, and feeling about these acute experiences. Many patients who demonstrate grooming behavior, for example, develop marked delusions of parasitosis and spend many hours examining their skin and digging out imagined parasites. These delusions appear to develop out of early sequences of skin sensations and repetitive "grooming responses." Thus, in both man and lower animals, sequences of patterned behavior, such as the grooming response, take on an autonomy and centrality of their own. In man, the next step is the gradual cognitive development of a corresponding entrenched and stereotyped delusion (1).

Although he did not recognize the common mechanisms underlying automatic-compulsive behaviors and stereotyped expressions, Bleuler (14) listed a variety of repetitive behaviors that he called stereotypies. In these he included posture, movement, attitude, and thinking. He even mentioned stereotypies of drawing, music, writing, and speech (verbigeration). Bleuler considered these constrained modes of behavior most characteristic of catatonic schizophrenia, but he noted that they were also present in other forms of schizophrenia, including the paranoid type. We have previously discussed the many features that paranoid and catatonic schizophrenia have in common and their relationship to the amphetamine psychosis (7).

We have pointed out that a common attitudinal-postural mechanism may subserve both the motor stereotypies and the constricted perceptual and cognitive patterns (7, 15). We conceive of these postural mechanisms not as passive responses providing orientation in space but more as a vigorous outgoing behavior that is acting on and projecting sensorimotor apparatus onto the environment or as reaching out and selecting parts of space and objects to be seen, felt, and thought about. Qualitatively the nature of these mechanisms might fall somewhere between posture, attitude, and initiation of movement. These mechanisms could well initiate and coordinate the many modes of perceptual attention, including searching and orientation to the outside world; conversely, these mechanisms may direct attention between various external as well as internal cognitive sets.

An amphetamine-induced loss of initiative or distortion of the mechanisms that regulate the continuous flow of behavior is postulated as the factor underlying not only stereotypies but also the perseveration of perceptual-cognitive-attitudinal sets. Thus we found in our cats fixing of attention and attitudes as well as fixing of posture and patterned movements. In other words, the animal's attentive mechanisms are persistently directed to a certain aspect or part of the environment, even after the accompanying stereotypy has broken. These fixed attitudes are not unlike those observed in speed freaks who become "hung up" for hours, either on a puzzle or in examining-sorting compulsions, or in suspicious, repetitious scanning movements of the eyes. Thus, a marked tendency to maintain attitudinal sets, as well as the accompanying examining modes, is characteristic of chronic amphetamine intoxication in both man and animals.

By the same mechanism, thinking itself could become repetitious as a result of perseveration in one of the systems subserving perception and cognition. For example, it is possible that stimulation of a specific postural-attitudinal set might not only induce the motor components of grooming behavior but also tend to constrict perception toward the enhancement of minute objects and, in this way, potentiate the associated thinking process that leads to the delusion of parasitosis. By an analogous process, the scope of the all-pervasive attitude of curiosity and/or suspiciousness that characterizes incipient

paranoid schizophrenia or the beginning phase of amphetamine psychosis might become increasingly constricted until, under the influence of behavioral disorganization, increasing arousal, and/or fear, the individual's behavior evolves into a paranoid reaction.

Neurochemical Basis for Amphetamine-Induced Behaviors

Over the past several years there have been exciting developments in research attempting to fractionate the types of behavior induced by amphetamine intoxication and to ascertain which behavioral neurotransmitters mediate these specific behaviors. It has been demonstrated that amphetamine-induced release of the neurotransmitter dopamine, which is densely distributed throughout the nigro-neostriatal system (16, 17), is responsible for the stereotyped behavior (18–20), while norepinephrine mediates the amphetamine-induced hypermotility. The nigro-neostriatal dopamine system is known to have a marked effect on the postural and motor mechanisms associated with attention—a finding that is in keeping with the amphetamine-induced behavior observed in animals as well as in man.

Recent studies on animals with unilateral, lesion-induced degeneration of the nigro-neostriatal dopamine system have demonstrated that when L-dopa or amphetamine is administered to these animals there is spontaneous turning of the head to the side of the lesion and neglect of sensory stimuli or searching behavior on the contralateral side (21). In addition, McKenzie (22) has demonstrated that bilateral ablation of the olfactory tubercle in rats markedly reduces the sniffing stereotypy induced by stimulation of the dopamine receptors. The projection of the dopamine terminals into the olfactory tubercle (23)—the old motor nucleus of the olfactory brain—also fits well with the observation that amphetamine stimulates postural changes and head movements related to olfactory searching in macrosmatic animals.

Functionally there are additional indications that the rhinencephalic forebrain is mediating the type of behavior induced by amphetamine (15). Electrical stimulation of the pyriform cortex, the olfactory tubercle, the amygdala, and the insulo-orbital cortex produces various oral exploratory activities, such as rhythmic sniffing, gnawing, and licking movements (24). In man similar automatisms and rhythmical movements are accompanied by characteristic changes in consciousness in the course of psychomotor epileptic seizures. We have previously reported (15) that there is a dramatic similarity between the psychosis associated with temporal lobe epilepsy and amphetamine psychosis. Recently we have demonstrated that, following the blockade of norepinephrine synthesis, amphetamine induces a dramatic increase in rhinencephalic electrical activity, with subsequent seizures (25). More importantly, this catecholamine manipulation produces behaviors (e.g., reactive attitude) that are seen only at the end stages of chronic amphetamine intoxication.

In addition, it is now well known that haloperidol and pimozide, two drugs that primarily block dopamine receptors (26), are two of the most effective antipsychotic agents currently in use. Angrist and associates (27) have also demonstrated that d-amphetamine is only one to two times as potent as l-amphetamine in producing psychosis although the ratio of potency is 10:1 for other effects. This potency ratio for the elicitation of psychosis is quite consistent with the hypothesis of stimulation through dopaminergic mechanisms since there are similar dose-response relationships in producing experimental animal stereotypy (28) and in changing the comparative kinetics of the accumulation of norepinephrine and dopamine at synaptasomes (29).

Fuxe and Ungerstedt (30) have previously demonstrated that amphetamine-induced behavior is related not only to the type of catecholamine neurotransmitter activity, but also to the ratio of norepinephrine to dopamine. By appropriately blocking and stimulating norepinephrine and dopamine mechanisms, they demonstrated that a strong norepinephrine-to-dopamine ratio is associated with exploratory locomotor behavior; when the ratio is reversed, an exploratory stereotypy is produced. When norepinephrine is depleted and, in addition, dopamine activity is enhanced by the administration of L-dopa, the exploratory stereotypy becomes highly constricted and compulsive. Gunne and Lewander (31) have demonstrated that *acute* amphetamine intoxication in animals primarily depletes norepinephrine, whereas *chronic* amphetamine intoxication depletes both norepinephrine and (to a lesser degree) dopamine.

When both norepinephrine and dopamine are depleted, important behavioral effects are induced through loss of the righting reflexes (32), and the catecholamine receptors become supersensitive to such receptor stimulants as apomorphine (21). Thus catecholamine depletion may be quite important in setting the stage for a supersensitive response to amphetamine. It may be that the depletion of norepinephrine and/or dopamine, as well as the disturbance of the balance between the two neurotransmitters, may have so sensitized the catecholamine neurons that additional amphetamine stimulation produces the hyperreactive state observed in our cats both in the later stages of chronic amphetamine intoxication and following the blockade of norepinephrine synthesis.

In conclusion, it is important that the amphetamine psychosis be regarded as an *evolving* sequence of behaviors that appears in several stages and cannot be explained on the basis of a single neurotransmitter effect. The physiological as well as the behavioral state is qualitatively different in the various stages of chronic amphetamine intoxication. Thus, in the model psychosis based on chronic amphetamine intoxication, the effect of the drug in further stimulating the altered psychological state of an animal resulting from previous intoxication, as well as stimulating depleted supersensitive norepinephrine and/or dopamine neuronal systems, is qualitatively different from the effect of the drug on a naïve animal. This line of reasoning is consistent with our thesis that each evolving behavioral state of amphetamine psychosis provides a base for the subsequent manifestation of the psychosis.

The Dream-Protein Hypothesis

BY ERNEST LAWRENCE ROSSI, PH.D.

Recent studies of learning and memory indicate that new experience is encoded by means of protein synthesis in brain tissue. The author reviews the literature on diet, nutrition, dreams, and REM sleep and finds support for the hypothesis that dreaming is a process of psychophysiological growth that involves the synthesis or modification of protein structures in the brain and that serves as the organic basis for new developments in the personality. The author outlines a series of experiments to further test the validity of this hypothesis. The implications of this research for a "growth" or "psychosynthetic" orientation in psychotherapy are discussed.

RECENT RESEARCH in the biology of learning and memory typified by the work of Hyden (1) indicates that new learning and behavior are encoded in the synthesis and/or modification of protein structures in brain cells. This statement of the relationship between biochemical events (protein synthesis) and behavior (new learning) is sufficient for behavior therapy but the language of psychodynamic psychotherapy requires the inclusion of phenomenological events. The relationship between phenomenological events and behavior is explored by the traditional methods of psychiatry and psychology (clinical interview, psychodiagnostic testing, etc.) but thus far the relationship between biochemistry and such events as dreams and fantasies has received little theoretical formulation or empirical support. This suggests the need for a dream-protein hypothesis: dreaming is a process of psychophysiological growth whereby dramas played out on a phenomenological level involve the corresponding synthesis and/or modification of proteins in the brain; this synthesis serves as the organic basis for new developments in the personality.

Studies that support the dream-protein hypothesis can be drawn from the vast body of research that uses rapid eye movements (REM) as the index of dreaming. These involve both the relationship between protein synthesis and dreaming and the relationship between dreaming and new developments in the personality.

Dr. Rossi is Extension Instructor, Department of Social Sciences, University of California at Los Angeles, and an analyst at the C.G. Jung Institute of Los Angeles; his address is 10486 Santa Monica Blvd., Los Angeles, Calif. 90025.

The author wishes to acknowledge the assistance of Ms. Jo Ann Boorkman, Computer Search Analyst, UCLA Information and Biographical Service Section, in obtaining a portion of the references for this paper through MEDLARS Computer Search no. 101726/R001, which was subsidized by the National Library of Medicine.

PROTEIN SYNTHESIS AND DREAMING

A MEDLARS computer search covering the research literature from January 1969 through June 1972 on the relationship of diet and nutrition to dreams and REM sleep yielded 181 citations, of which about 20 percent dealt with the relationship between protein synthesis and dreaming. The most direct evidence for this relationship in humans is the finding that alterations in protein metabolism achieved by either blocking or supplementing amino acids in the diet has an effect on dreaming. It has been found by Lester and colleagues (2), for example, that low-phenyl-alanine-tyrosine diets result in a systematic reduction in REM sleep. They then found this effect could be reversed so that the percentage of REM sleep was increased when tyrosine (in capsule form) was added to the diet. Furthermore, it has been found by other investigators (3) that tryptophane has a small but statistically significant effect in increasing REM sleep. The deprivation or supplementation of amino acids that are associated with ribonucleic acid (RNA) and protein synthesis is thus directly related to REM sleep in humans.

Our literature search turned up many more references to experimental work with animals than with humans. The general finding documented by numerous animal studies (4–7) supports the finding of the studies with humans, i.e., that deprivation or supplementation of amino acids in the diet results in corresponding effects on REM sleep. In no case, however, was there a study designed specifically to evaluate this relationship. Most of the studies were motivated by interest in the neurochemical origin of REM sleep, the role of amino acids in the transmission of the nervous impulse, or the action of monoamine oxidase inhibitors on REM sleep, rather than by the concept embodied in the dream-protein hypothesis. Although the results of these studies are all in the direction that would be predicted by the dream-protein hypothesis, new studies specifically designed to test the validity of the hypothesis are now called for. Three general approaches to validating the dream-protein hypothesis seem possible.

1. In table 1, the three-stage process in the synthesis of proteins from amino acids and RNA is outlined, together with a listing of some of the metabolites and chemical agents that have been used (8, 9) to facilitate or retard each stage in learning and memory experiments. In general the dream-protein hypothesis would predict that agents that facilitate any stage of protein synthesis would tend to increase REM sleep, while those agents which block a stage of protein synthesis should decrease REM sleep. This prediction has been amply verified at the

amino acid stage but not at stages closer to the synthesis of RNA and proteins. Such verification would be needed to further confirm or disprove the dream-protein hypothesis.

2. During the past decade, innovations in biochemical analysis that permit the isolation and measurement of extremely small amounts of macromolecular RNA, of such enzymes as cholinesterase (10), and of neural growth factors (11) have enabled researchers to determine how these substances affect memory and learning. In essence these studies indicate that new developments in learning and behavior may be associated with changes in the synthesis and/or structure of RNA. If researchers can now detect changes in the presence of RNA, cholinesterase, or neural growth factors at the locus of dream activity (e.g., the visual cortex) during the REM state, they will have provided further support for the dream-protein hypothesis.

3. The relationship between protein intake and dreaming has been more difficult to describe. Although extreme protein deprivation does result in EEG abnormalities (2), I have not yet found any studies dealing directly with the relationship between the deprivation of protein or protein precursors (apart from the amino acid studies cited above) and REM sleep. Three types of research could clarify this relationship: 1) neuroanthropological studies of the effect of extreme protein deprivation on the REM sleep of population groups that are subject to these specific types of malnutrition (12); 2) REM studies on people who subject themselves to macrobiotic diets that are deficient in proteins (my preliminary interviews with a number of such people yielded the expected subjective report of decreased dreaming or dream recall while they were on such diets); and 3) animal studies that relate protein and amino acid deprivation to REM sleep (13).

TABLE 1
Agents That Have Been Used to Facilitate or Block Protein Synthesis

Item	Increase Uptake or Synthesis	Block Uptake or Synthesis
Amino Acids	Dietary amino acids: tryptophan, tyrosine, etc.	Amino acids restricted
RNA	Yeast RNA, malononitrile, magnesium pemoline (?), soluble RNA	8-azaquanine, actinomycine-D
Protein	Dietary proteins, malononitrile (dimers and trimers)	Restricted diets, puromycin, puromycin amino nucleoside, cycloheximide

DREAMS AND PERSONALITY DEVELOPMENT

Just as Snyder (14) has organized many of the diverse and apparently unrelated findings of REM research into an evolutionary theory of dreaming on the phylogenetic level, we may also apply the findings of much REM-related research to the ontogenetic development of the individual's personality. I shall summarize those findings which bear upon the integrative or psychosynthetic functions of REM sleep that are most directly relevant to the dream-protein hypothesis.

1. Dreaming is initiated and primarily regulated by internal brain processes rather than by external stimuli from the environment (15). That is, dreaming is a process that is important for internal developments within the brain itself rather than for handling external stimuli. In an evolutionary theory of dreaming, Snyder expressed this conception well:

> [The REM state] is not a condition of partial arousal intermediate between sleep and waking, but now appears to be among the most extraordinarily intense activations yet discovered in the normal functioning of the central nervous system. Although similar in many respects to highly aroused waking, there are good reasons for thinking that the functional organization of central nervous activity is quite different from waking, and that the stimulus which originates this activation is intrinsic to the brain itself (14, p. 123).

Meissner (16) has outlined the neurophysiological mechanisms characteristic of REM activation that "suggest that the striking activation of limbic structures in rhombencephalic sleep has a specific integrative function which serves to maintain the effective organization and integration of emotional and cognitive experience." The conclusion therefore seems inescapable: the state of dream consciousness concerns the organization and synthesis of internal data (e.g., personality development), while the awake state of consciousness deals primarily with the processing of external sensory data from the environment.

2. The REM state occupies up to 50 percent of the sleep time of neonates and children (at ages when learning and personality formation is greatest) and then decreases to 20 to 25 percent with increased age, as the capacity for new learning and personality growth becomes relatively less (17).

3. Recent studies (18) of the dreams of children and adolescents indicate that the typical dreams of normal children revolve about recreational activities and as such "appear most simply to represent extensions of the child's waking ego impulses to exploration and manipulation of the environment." The REM state can thus be understood as a period during which internal programs are being synthesized and consolidated so they can later be actualized in personality and behavior change.

4. Dement and associates (19) have recently summarized findings from their laboratory which demonstrate that REM sleep is necessary for the optimal control and integration of drive systems (aggression and sex) in laboratory animals even though it is not necessary for life itself. Recently Hartmann and his co-workers (20) have concluded from studies with humans that "psychic pain or psychic disequilibrium with changing defense patterns" are associated with an increase in REM sleep. The

subject who required more REM sleep "is relatively anxious and depressed, and his life style involves change and worry." These conclusions are exactly what one would expect if dreams had a psychosynthetic function in maintaining the growth and stability of the ego, since more REM sleep would be required during periods of more active personality growth, change, and stress.

5. Recent studies of the correlation between REM sleep and the process of change in psychotherapy provide interesting confirmation for the above. Freedman and associates (21), for example, reported that "striking and consistent correlations were discovered between the length of the fourth dream period and the [psychotherapy] session variables of self-satisfaction, wish fulfillment, elation, and control." I have discussed elsewhere how these types of variables can be understood as indications that a process of psychological growth (psychosynthesis) is taking place (22). This type of study thus tends to confirm that there is a direct relationship between dreaming and personality growth as stipulated by the dream-protein hypothesis.

PSYCHOTHERAPEUTIC IMPLICATIONS

Validation of the dream-protein hypothesis would provide a biological basis for modern theories of personality change, growth, and development. Most workers have been so overwhelmed by Freud's concept of psychoanalysis that they have tended to overlook psychosynthetic processes. Just as the biochemical basis of life may be conveniently divided into anabolic and catabolic processes, so one may posit a dynamic equilibrium within the phenomenological realm between psychosynthetic processes (whereby entirely new and more complex psychological experiences are created) and analytic processes (whereby a breakdown of inner experience into simpler parts is evident).

The growth or psychosynthetic orientation is actually the common denominator of a very wide range of the apparently diverse "schools" of psychotherapy that have developed since Freud (23). Apart from the ideas of such early ego psychologists in the Freudian psychoanalytic framework as Hartmann, Kris, and Lowenfeld, Jung's central concept of individuation, Adler's concept of the creative self, and Rank's emphasis on the artist-type may all be understood as efforts to explore the synthetic or creative aspects of personality development. The existential approaches of Binswanger, May, and Frankl emphasize the complex coping methods by which a person actually creates his existence and world view. In recent years the client-centered, humanistic, and gestalt psychologists have all elaborated approaches and attitudes toward psychotherapy that focus on a growth orientation.

While the growth orientation frequently has been presented in a global and loosely defined manner by many of these theorists, the psychosynthetic approach of Assagioli (24) and the autogenic meditation methods of Schultz and Luthe (25) have introduced a certain degree of precision and scientific control in facilitating personality development. Assagioli, for example, has pioneered in the development of "meditation" methods by which the patient allows his imagination to elaborate a standard series of emotionally significant patterns of internal imagery. This elaboration of internal imagery may have important diagnostic significance; more importantly, however, the growth-oriented therapist uses this approach to facilitate the actual synthesis of new psychic structures that can become the nuclei for new developments in the personality. I have recently extended this approach by illustrating in detail how symptoms of "psychopathology" can be understood as breakdowns in the natural processes of personality development (22). This analysis of these psychosynthetic processes, as outlined in a series of "phenomenological equations," suggests how they may be used to develop further approaches to facilitating personality development in psychotherapy.

The obvious drawback of the phenomenologically oriented growth approaches to psychotherapy is that they lack the foundation in biology and chemistry that most workers since Freud consider so important for any psychodynamic psychology. Concepts of libido, genetic determination, hormonal regulation, imprinting, and most of the other current variables of biological psychiatry are sometimes useful in dealing with the global or molar aspects of personality but they are obviously unable to account for the intricate variability found in individual fantasies and dreams that continually change with life experience. The dream-protein hypothesis is a means of directly relating these subjective events of personality growth to biochemical events. If the dream-protein hypothesis can be further validated it would be a major step in establishing a biochemical foundation for personality dynamics.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its annual Manfred S. Guttmacher Award for 1974. The award is given for any outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or any other work, including audiovisual presentations, submitted to or presented at any professional meeting or published during the year ending December 31, 1973. The award, which includes an honorarium of $250 and a plaque, will be presented at the Convocation of Fellows at the annual meeting in Detroit, Mich., May 1974.

Anyone who wishes may apply to receive the award by submitting five copies of the work as well as five abstracts to Jonas Rappeport, M.D., Chairman, Guttmacher Award Board, American Psychiatric Association, 1700 18th St., N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

The deadline for submissions is January 1, 1974, and to be considered any entry must be in Washington by that date.

Indian Education: A Human Systems Analysis

BY CARL A. HAMMERSCHLAG, M.D., CLAYTON P. ALDERFER, PH.D., AND DAVID BERG, M.A.

The problems of Indian boarding schools are examined in the light of both systems theory and data from interviews and questionnaires conducted at one school. The authors conclude that the schools have failed to define their primary task—to educate or to handle children with behavior problems. More importantly, the impact of the whole educational system perpetuates the Indians' powerlessness and dependency on the government. The authors express the hope that, if there is more community involvement in the schools, this will lead to greater assumption of responsibility by Indians in other spheres.

THE BUREAU OF INDIAN AFFAIRS (BIA), charged with the education of American Indians, today operates more than 200 schools in 17 states. Of the approximately 200,000 school-age Indian children, 35,000 are in BIA boarding schools, 16,000 are in day schools, and 24,000 are housed in BIA dormitories while attending public schools. Of the 35,000 children in boarding schools, more than 12,000 attend off-reservation boarding schools, which for the most part provide a high school education for Indian children who have completed the eighth grade. The remainder are in on-reservation boarding schools; 8,000 of these are elementary school students, nine years old or under (1). Enrollment in BIA boarding schools is increasing; indeed, it has doubled in the 1960s.

The history of the boarding school experience, its inadequacies, and its archaicisms were first commented upon by Merriam in 1928 (2). Studies since have concluded that, as the cultural and educational backgrounds of Indian children become more like those of white children in public schools, the educational achievement of Indian children will more closely match that of white children (3–5). To many Indian people that implies a not very subtle attempt to sow the seeds of cultural dissolution, to use the schools as an instrument of Indian cultural annihilation. There are still rituals among tribes today to cleanse their children of white contamination on their return from boarding schools. This study explores the impact of a boarding school system on both students and staff members who live, learn, and work there.

Read at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

Dr. Hammerschlag is Mental Health Consultant, Indian Health Service, 4212 North Sixteenth St., Phoenix, Ariz. 85016. At the time of this study, Dr. Alderfer and Mr. Berg were both with the Department of Administrative Sciences, Yale University, New Haven, Conn., where Dr. Alderfer is Associate Professor and Mr. Berg was a graduate student.

THE SCHOOL SYSTEM

The school studied, located in a major southwestern urban setting, has approximately 700 students, aged 14 to 22 years, and 200 staff members. All the students are Indians; most of the teaching and administrative personnel are non-Indian. At least 60 percent of the student body enters this boarding school for so-called "social reasons," which include extreme poverty, large families, language difficulties, and behavior problems in other schools. Because so many children come to the school for these reasons, there is considerable ambiguity among the staff as to whether the primary mission of the school is one of behavioral control or teaching.

For example, the dormitory attendants, who are charged with the management of 120 students per dorm, see their jobs as maintaining order and resolving immediate crises. The teaching staff see their roles as instructional, but students who do well in class are not necessarily the ones who also behave well outside the classroom. There is little interpenetration of the boundaries between these distinct task groups at any time. When it does occur, it usually concerns decisions about the dismissal of students with behavior problems. If the greatest articulation of structure exists for a secondary task of the system (such as behavioral control) and the purported primary task (i.e., education) remains isolated, the system is in trouble.

The concept of boundary is an aspect of open systems theory that treats organizations as systems whose survival requires the continuous exchange of materials with the environment (6–8). If the boundary is too permeable it invites inundation, chaos, and disorganization, whereas an impermeable boundary becomes a barrier that causes death through entropy. There are boundaries that separate the organization from its environment and those which are internal to the organization. These internal boundaries separate task systems from each other. The authority for these separate internal operations (dorm, teaching, guidance) is delegated by top management to subordinates. The viability of the subsystem, and ultimately of the total organization, is dependent on successful boundary transactions between these adjacent subsystems.

In the school's case, each subsystem functions as if it were totally independent and involved in tasks that are perceived as mutually exclusive. For example, a dormitory head telephoned a guidance counselor at midnight to say that a student was drunk and disorderly and asked that he come over right away. The counselor replied, "I don't think I can do much counseling with the student in

Health is a research hospital and accepts patients only upon referral from a physician, our sample may not be representative of the general population of depressed patients.[3] Nevertheless, our data support the hypothesis that many depressed patients are referred to hospitals without adequate trials of antidepressant drugs as outpatients. Perhaps many hospitalizations could be averted if antidepressants were better used.

While some patients may not receive adequate drug therapy because of the sudden onset of their illness and emergency referral, the attitudes and behavior of the prescribing physician may be responsible. In some instances there may be a bias against the use of drugs in favor of psychotherapy alone. In others, unfamiliarity with antidepressants and fear of side effects may account for their not prescribing these drugs or prescribing them only at low dosages. Incorrect diagnoses, as well as a lack of knowledge of the usefulness of antidepressants, might also contribute to the use of the wrong drugs.

One factor that may have contributed to the low dosage of tricyclics in some of these cases was the use of fixed proprietary combinations. Five patients in the group that had been inadequately treated were receiving fixed combinations of perphenazine and amitriptyline (Triavil). For this combination to be effective, either 12 or 24 mg. per day of perphenazine[4] must be given to achieve a minimally effective dosage (150 mg./day) of amitriptyline. Physicians may be reluctant to administer this much phenothiazine to a patient with primarily depressive symptoms.

It is tempting to suggest that the further education of physicians is the solution to the problem of inadequate drug treatment of depression by physicians in the community. In fact, this may be a partial answer. However, information on antidepressants and their use has long been available and is presumably incorporated into existing medical school, residency, and continuing education curricula. If our suggestion for a larger study of the actual patterns of drug prescription in the community is followed, perhaps information on the causes of inadequate drug treatment could be obtained and recommendations made accordingly.

CONCLUSIONS

Our clinical impression that many depressed patients are referred for hospitalization before they receive adequate drug treatment as outpatients was confirmed in a sample of 51 consecutively admitted depressed patients at the National Institute of Mental Health. Only 20 percent of our sample were receiving drug treatment that was adequate for depression at the time of their referral. Twenty-five percent were receiving antidepressants at dosages lower than those generally considered effective. Eighteen percent received drugs other than antidepressants and 37 percent were not receiving drugs. Of those patients in our sample who were treated with adequate dosages of antidepressants in the hospital, two-thirds responded. Our data suggest that many depressed patients in the community may not be receiving adequate drug treatment for their illnesses.

Inadequate drug treatment for depression may result from the physician's unfamiliarity with or bias against use of these drugs. We suggest that a larger study of actual patterns of drug prescription in the community be undertaken to confirm our preliminary findings and to seek the causes for inadequate drug treatment, so that appropriate educational programs can be undertaken. Adequate drug treatment of depressed patients may in many cases obviate the need for hospitalization.

Single Versus Divided Daily Dose of Trimipramine in the Treatment of Depressive Illness

BY M.Z. HUSSAIN, D.P.M., AND Z.A. CHAUDHRY, M.B.

A group of 56 patients with depressive illnesses were administered either a single daily dose or a divided daily dose of trimipramine on a random basis. Results of the treatment showed several advantages for the use of a single daily dose: a trend toward better therapeutic improvement, a significant decrease in the side effects of insomnia and fatigue, and more regular consumption of the medication.

A COMMON PRACTICE in the pharmacotherapy of depressive illness is to prescribe antidepressants in three or four divided doses during the day. Such a practice does not seem to have a scientific basis. Although single daily doses have been recommended for tricyclic antidepressants (1–4), few studies have systematically evaluated a single versus a divided regimen of these drugs.

This investigation was designed to examine the differences in divided and single dose administration of trimipramine in treating depressive illness. Trimipramine is a tricyclic antidepressant of proven efficacy (5, 6) and comparatively few side effects.

METHOD

Fifty-six patients of both sexes suffering from depressive illnesses, with major depressive symptoms including retardation, agitation, anxiety, sleep disturbance, or somatic complaints, were admitted to the trial. All patients were under 65 years of age. Seventy-five 100 mg. scored tablets of trimipramine were dispensed to each patient in a sealed envelope containing directions for taking the medication. The patients received instructions to take either divided doses of half a tablet (50 mg.) twice a day for the first day and four times a day thereafter or a single dose of one tablet (100 mg.) on the first night and two tablets (200 mg.) each night thereafter. These instructions were enclosed in the envelopes in random order and the envelopes were marked without the therapist's knowledge. After the trial period of four weeks the tablets that were returned unused were counted and the number recorded.

Before commencing treatment, each patient's symptoms were evaluated on the basis of the Hamilton Rating Scale for Depression (7) and the Zung Self-Rating Depression Scale (8). These scales were administered again after two and four weeks of treatment.

The authors are with the Psychiatric Centre, Victoria Union Hospital, 1200-24th St. West, Prince Albert, Sask., Canada, where Dr. Hussain is Senior Psychiatrist and Dr. Chaudhry is a resident in psychiatry.

RESULTS

Four of the 56 patients initially treated discontinued use of the drug during the first week of treatment because of side effects. Two other patients dropped out and did not complete the treatment, and one patient was withdrawn in the first week for treatment with ECT because of the increasing severity of his depression and suicidal preoccupation. Of the remaining 49 patients, 26 were in the single-dose regimen (SDR) group, and 23 were in the divided-dose regimen (DDR) group. A comparison of the two groups by age, sex, and duration of illness is presented in table 1.

The number of tablets returned was subtracted from 75 (the number issued) and this figure was divided by the number of days in the trial. This gave the patients' presumed daily consumption of the drug during the trial period of treatment. The mean daily consumption rate for the SDR group was 181 mg., and for the DDR group, 162 mg.

The mean scores of the two groups on the Hamilton Rating Scale and the Zung Self-Rating Depression Scale are shown in table 2. For the Hamilton Rating Scale, the comparison of pretrial scores with scores of the two later periods of treatment shows a significant improvement during the trial period. The difference between the two groups did not reach a significant level, but a trend toward a better response was present in the SDR group.

TABLE 1
Characteristics of Single (SDR) and Divided (DDR) Treatment Groups

Characteristic	SDR Group (N = 26)	DDR Group (N = 23)
Sex		
Men	9	7
Women	17	16
Age (mean±S.D.)	42.2±8.4	44.9±9.7
Duration of illness (in months)	7.2±5.6	6.6±6.1

TABLE 2
Comparison of Group Scores on Depression Scales Over Treatment Period

Treatment Period	Hamilton Rating Scale		Zung Self-Rating Scale	
	SDR Group Mean±S.D.	DDR Group Mean±S.D.	SDR Group Mean	DDR Group Mean
Initial	27.3±6.7	26.2±6.4	63	61
Two weeks	12.4±6.1	16.5±7.8	43	48
Four weeks	9.3±3.8	11.2±4.5	34	36

There were no significant intergroup differences in the mean Zung Scale scores initially. At the end of four weeks the mean Zung Scale scores were within the normal range. The same trends were observed when the mean scores of the 20 items of the Zung Scale were grouped to measure affective, biological, and psychological symptoms.

The effect of the treatment on individual symptoms was measured by calculating the proportion of patients completing the trial in each group who were free of particular symptoms at the end of each assessment. A significant result was that in the second week's assessment the symptoms of insomnia and fatigue decreased most in the SDR group.

All symptoms associated by the patients with drug intake and reported spontaneously by the patients regardless of whether or not the therapist agreed were defined as side effects. Patients were asked to report any effects from the medication, yet no specific inquiry into such reactions was made. Some patients had multiple side effects. Four patients withdrew from the investigation because of side effects, three of whom were on divided doses. Two of these patients complained of dizziness, blurred vision, and sleepiness, and one complained of depersonalization and inability to concentrate or think clearly. The fourth patient, who was on a single nightly dose, complained of inability to wake up in the morning and excessive drowsiness. Table 3 shows the data on side effects. All patients received routine physical examinations and laboratory tests as well as complete blood counts and urinalysis at the beginning and end of the trial. These tests showed no abnormal findings.

DISCUSSION

Although there is much variation in the rate of metabolism of the tricyclic antidepressants among individuals, generally the absorption after ingestion is remarkably prompt. Maximum absorption takes place in the first 30 to 60 minutes after oral administration. Following this period the fall in serum level is rapid, and after a few hours even a massive overdose will produce only minute traces in the bloodstream (9). Normally 40 to 50 percent of a single dose can be recovered from the urine within four days, either as the drug itself or as one of its metabolites. Most of the drug is stored in body tissues; relatively high levels are found in neuronal tissue. These compounds do not leave the brain by simple diffusion into the bloodstream, where the concentration is low, but are released gradually from neuronal storage sites as they reform.

It seems evident that divided doses are not necessary for effective absorption and that therapeutic effects can be achieved adequately with single daily doses. Our results indicate an advantage for patients who received single nightly doses of trimipramine compared with those receiving divided doses. Although the difference in beneficial therapeutic result did not reach a level of significance, the depressive symptoms of insomnia and fatigue were significantly affected.

The incidence of side effects was significantly low. The higher incidence of side effects with divided doses could possibly be due to greater fluctuation in the level of the drug found in the serum after repeated doses. A significant positive correlation has been found between the level of tricyclic antidepressants in the plasma and their subjective side effects (10). A transient sedative effect that usually occurs between 30 and 60 minutes after oral administration of the drug may hinder the patient's activities during the daytime, but the same effect becomes most desirable at night, since insomnia is a troublesome feature of depressive illness. Administration of the drug at night also makes prescription of hypnotics unnecessary, thus reducing treatment cost and preventing possible interaction between different medications.

In this investigation single-dose consumption was more regular than consumption for repeated doses, confirming previous findings (11, 12) that a regimen consisting of a single daily dose is more reliable than one consisting of multiple doses. A single dose is more convenient for the patient and staff and gives nurses more time to take an active therapeutic role in patient care. A large single dose is also less expensive than its equivalent amount in divided doses.

The results of this investigation suggest that it is not necessary to give tricyclic antidepressants in divided

TABLE 3

doses or to use sustained-release preparations (13) in order to achieve therapeutic effectiveness. Dosage should be 150 mg. or above, as smaller doses are probably too low to have much therapeutic effect (14, 15).

"The Fitness Factory," Part I: The Psychiatrist's Role in Determining Competency

BY ROBERT LLOYD GOLDSTEIN, M.D.

This article is the first in a series on the work of the New York City Forensic Psychiatry Clinic, which performs mental competency evaluations of defendants appearing before the New York City Criminal Court. The author describes the clinic's philosophy regarding competency and contrasts its roles before and after the enactment of the new Criminal Procedure Law that granted considerably broader powers to the clinic.

> The psychiatrists, as usual, will not agree about him, they will argue in front of a jury who will not understand what it is all about, and there is every chance that he will get the benefit of the doubt, in which case he will be sent to spend the rest of his days in an asylum.
>
> —SIMENON (1, p. 137)

THROUGH A COMBINATION of historical accident, social evolution, and pragmatic necessity, the infant science of psychiatry has become an inextricable cog in the machinery of the law, just as it has become a sometimes embarrassing but firmly entrenched member of the medical-scientific community. A learned and distinguished body of jurists, legal historians, forensic psychiatrists, and other social critics has seriously questioned the wisdom of a growing tendency to attribute to psychiatrists inflated powers of diagnosis and prediction in what is still an uncharted and poorly understood area—the interface of psychiatry, law, and society (2–4).

Nevertheless, with increasingly crowded courtrooms, greater pressure to understand and control antisocial patterns, and the widespread myth (unfortunately not limited to laymen) that psychiatry does have all the answers, an uneasy *mariage de convenance* has been produced that is likely to be with us for some time.

This article is the first in a series of articles on the work of the Forensic Psychiatry Clinic—a large clinic operating under the aegis of the New York City Criminal Court—in evaluating the competency of criminal defendants. The larger issues of the place of psychiatry in the courtroom, the civil rights of criminal offenders, and the overall structure of our national legal-psychiatric-penological establishment are well beyond the scope of

Dr. Goldstein is Medical Director of the Forensic Psychiatry Clinic, New York City Criminal Court, 100 Centre St., New York, N.Y. 10013, and Clinical Instructor in Psychiatry, New York University.

these articles and will be alluded to only when appropriate to the discussion (3–6).

CLINIC PHILOSOPHY CONCERNING COMPETENCY

The Forensic Psychiatry Clinic, since its inception in 1955, has served the New York City Criminal Court in a variety of areas covering several stages of the legal process. The clinic has performed competency screenings and pretrial and presentencing evaluations and has offered recommendations to the court and the office of probation for planning and implementing realistic rehabilitative programs for the mentally ill offender. The clinic staff—psychiatrists, psychologists, and social workers—have all had extensive experience in forensic psychiatry. Staff members come from a variety of training backgrounds and theoretical orientations (e.g., psychoanalysis, behavior therapy, community psychiatry), but all try to steer a steady course between the Scylla of Szaszian iconoclastic doublethink and the Charybdis of the doctrine of parens patriae, which would too eagerly see everyone sent off to the hospital "for treatment." Although proponents of the latter view undoubtedly have the best of intentions, they fail to consider the "unfairness of substituting a benevolent purpose for due process of law where individual liberty is at stake, especially if the benevolent purpose has in reality fallen short of its promise" (7).

The prevailing philosophy of the clinic is that "every man should have his day in court," regardless of whether or not he is mentally ill, provided he is able to satisfy the threefold common law test for competency, which specifies that the defendant: 1) must be capable of understanding the nature and object of the proceedings against him, 2) must be able to comprehend his own condition in relation to such proceedings, and 3) must be able to assist in his defense in a rational or reasonable manner.

We would concur with McGarry, who believes that:

> Unless their criminal charges can be otherwise disposed of, mentally ill defendants are far better served by an expeditious return for trial than by indefinite commitment in a mental hospital while awaiting trial .... Among psychiatrists a bias exists against returning the mentally ill for trial and ... this has led to considerable wasting of human lives and unnecessary deprivations of freedom (8, p. 1181).

We have attempted to avoid such pitfalls by addressing ourselves specifically to the question of competency in its narrowest sense and returning even the seriously disturbed or dangerous individual to face the court if he is competent within the general guidelines of Anglo-Saxon common law.

We have attempted to communicate these objectives to the court, the district attorneys, and the defense counsel. As McGarry has pointed out elsewhere, the confusion and misapprehensions that exist concerning competency, mental illness, and criminal responsibility are not limited to psychiatrists, but unfortunately are shared by experienced judges, lawyers, and laymen (9). The courts have frequently equated the various types of psychiatric examinations, losing sight of the circumscribed focus of the competency evaluation. Evaluation of the defendant's mental state at the time he is to appear for trial is frequently confused with determining his mental state and capacity for responsibility at the time of his offense or with assessing his problems in their entirety, with an eye toward recommending a long-range plan for management or treatment.

TABLE 1

Case Dispositions Following Competency Evaluations in 1969–1970

Disposition	Number of Cases	Percentage of Cases
Evaluated by clinic	1,085	
Competent (returned to court)	608	56.0
Possibly incompetent (referred to hospital)	477	44.0
Found competent at hospital	201	18.5
Committed to state hospital	276	25.4
Total returned to court	809	74.6

CLINIC PROCEDURES BEFORE ENACTMENT OF THE NEW CRIMINAL PROCEDURE LAW

Before enactment of the new Criminal Procedure Law in September 1971, the clinic performed competency screening examinations—brief clinical evaluations to determine, informally, whether the defendant seemed competent. If he seemed competent, he was promptly returned to the court. If there was any doubt about his competency, he was sent to a metropolitan hospital prison psychiatric ward for further observation and examination. Only in the hospital could a formal legal determination of incompetence be made.

The demand for competency screening examinations increased dramatically between 1967 and 1970; 601 examinations were performed in 1967–1968, 837 in 1968–1969, and 1,085 in 1969–1970. The factors contributing to this increase and some of the motives for requesting these examinations were discussed in a previous report from this clinic (10). During each of these years approximately 44 percent of the cases seen for screening were referred to the hospital. This meant that over half of the defendants referred to the clinic were able to return directly to the court to face their charges, without unnecessary interruptions, delays, or interim hospitalization.

Table 1 presents the statistics for the outcome of competency evaluations in 1969–1970, which is representative of the period before enactment of the new Criminal Procedure Law. In this year 42 percent of the defendants who were referred to the hospital were able to return to the court after brief periods of observation and evaluation, as well as some form of therapy in some cases. Thus, only 25.4 percent of the defendants originally referred to the clinic for competency evaluation required

commitment to a state hospital. The remainder of the defendants were returned to the court, through the combined efforts of the clinic and the hospital prison service.

The fact that almost half of the patients sent by the clinic to the hospital for competency evaluation could be returned rather quickly to the court demonstrated the inadequacy of the clinic's screening procedure. Many unnecessary hospitalizations resulted—a sad reflection on psychiatric standards, economic efficiency, and concern for the civil liberties of the patients. Time restrictions and procedural limitations necessitated rapid and sometimes inconclusive evaluations of defendants, with no provision for delay or recall. This often led to the hospitalization of agitated, excited, or confused defendants who were suffering from acute drug or alcohol intoxication, an acute situational reaction, or an acute psychotic episode. When they received some appropriate supportive therapy, these defendants usually reintegrated rather quickly and certainly could have been declared competent by the clinic if we had had the necessary facilities for management and the time for reevaluation.

Cases of malingering and patients with fluctuating paranoid symptomatology, situational reactions of belligerence and negativism, and other equivocal but not unusual clinical states were difficult to evaluate and would probably be sent on to the hospital by cautious and concerned doctors "just to be on the safe side." In a smaller number of cases, misguided therapeutic zeal seemed to be responsible for the referral of an obviously disturbed defendant to the hospital in the hope that the defendant would receive prompt treatment despite his obvious competence. As a rule the hospital would quickly recognize his competence and send him right back.

CHANGES IN CLINIC PROCEDURES AFTER ENACTMENT OF THE NEW LAW

The new Criminal Procedure Law went into effect in New York State on September 1, 1971. The competency issue was covered in Article 730, "Mental Disease or Defect Excluding Fitness to Proceed." The time-honored but frequently misleading terms "competency" and "incompetency" were replaced with new and, one hopes, more precise terminology that differentiates the individual who is "fit to proceed" or has the "capacity to proceed" from the individual who is "unfit" or "incapacitated." The incapacitated individual is defined as one who "as a result of mental disease or defect lacks the capacity to understand the proceedings against him or to assist in his own defense" (1).

The new law provided that competency examinations were henceforth to be performed on a formal basis by the Forensic Psychiatry Clinic. Specific rules and procedures were jointly adopted by the Judicial Conference and the Department of Mental Hygiene. These new procedures and the concomitant expansion of the work load led to a large-scale reassessment of the professional focus and redeployment of manpower within the clinic and to a greater emphasis on the issue of fitness in conferences, seminars, and supervision. The result was the creation of what we wryly refer to as "the fitness factory."

Now each defendant referred for fitness evaluation under a court order is examined by two clinic psychiatrists. In doubtful cases he may be recalled for further examinations. In the interim he is housed in a special section of the jail where doctors, nurses, and paraprofessional workers are available to administer medication and counseling in the atmosphere of a modified therapeutic community. A sufficient amount of time for observation is thus provided to make meaningful, well-substantiated reports to the court. The clinic psychiatrists have the opportunity to discuss and compare their findings, draw upon the testing tools and expertise of the psychologist when necessary,[1] and in most cases confer with the attorneys involved concerning the defendant's ability to effectively assist counsel in planning a rational defense.

The defendant may be found fit by the two psychiatrists and returned to the court or be found unfit and committed by the court to a state mental institution. If the psychiatric examiners are unable to agree, a hearing is scheduled to settle the issue; a hearing may also be scheduled in response to a motion by the court or either attorney.

A review of the clinic's performance from January 1972 through May 1972 will serve to illustrate its role under the new Criminal Procedure Law. During this period 338 subjects were examined for fitness (each by two psychiatrists). Of these, 240 defendants (71 percent) were found fit, which allowed their court action to proceed promptly, and 71 (21 percent) were found unfit and were committed by the court to a state hospital. In the remaining 27 cases (eight percent) a final decision could not be reached by the psychiatrists and, as provided under the new law, the defendants were sent to the prison service of a metropolitan hospital for more prolonged and intensive evaluation of their mental condition. If the hospital prison service is able to return approximately half of these patients to the court, as it has in the past, the population found fit and returned to the court would represent 75 percent of the total.

These figures indicate that under the new system, with the clinic performing fitness examinations on a formal basis, the same percentage of defendant-patients is able to return promptly to the court as under the old system, which used inpatient hospital facilities to perform the bulk of the task. It seems warranted to assume that the clinic's "fitness factory" is able to make dispositions under the provisions of the new law as effectively as were the clinic and hospital together in the past. This means that a substantial burden can be removed from the already overtaxed municipal hospital's prison services and assures that scores of defendants will be spared unnecessary and wasteful hospitalization, transfer back and forth between grim institutions, and additional stigmatization and deprivation of individual freedom before they have

[1] The expanding role of the psychologist in competency determinations will be discussed in a subsequent article.

been convicted of any crime.

There seems to be a fairly consistent proportion (25 percent) of defendants who are found to be unfit or incompetent. The characteristics of this core group need further study and evaluation. At present it seems clear that members of this group can usually be detected by a clinic examination, with minimal need for psychiatric hospitalization to accomplish this objective.

DISCUSSION

Walter Bromberg has stated, "Psychiatrists have been employed as aides to the court in the evaluation of the mental states of accused persons for less than 150 years. In that time they have managed to evoke considerably more discord than have a dozen other types of expert witnesses" (12, p. 1343). Bromberg's article strongly suggested that the optimal utilization of psychiatric knowledge within the legal system is far from being realized. Karl Menninger has asserted that the illegal acts of criminals are the symptoms of mental illness and that the legal acts of the law enforcers are crimes (2). The disconcerting dialectic of Thomas Szasz depicts psychiatrists as ideologists of insanity, manufacturing madness in order to diminish man as a person and oppress him as a citizen (3, 4). In this intellectual climate, it is difficult to leave the lofty debates at the height of Olympus to chip away slowly and tediously at the foot of the mountain of unfinished research. Yet this is what we are attempting to do in our "factory." We are attempting to hone our diagnostic and evaluative tools to their sharpest, to discipline ourselves to focus on the issue of fitness per se, and to return defendants to the court whenever possible. Despite occasional patients with grave and pervasive personality disturbances, most mentally disturbed offenders are fit to participate in the proceedings against them and to make full use of their rights.

Mason (13), Robey (14, 15), and McGarry (8, 9) have helped to clarify the nature and goals of competency examinations under a variety of conditions. Robey's guide to conducting competency evaluations has been an indispensable clinical tool for our staff. Others have designed comprehensive questionnaires and psychological tests and described clinical clues that have seemed less reliable and helpful in dealing with our clinic's population (16–18). In fact, we have found no reliable shortcuts. Each case seems to demand a shrewd clinical appraisal; collateral information gleaned from the attorney, psychologist, previous hospital records, and other sources; and a touch of intuition, guesswork, and just plain luck.

It should be noted that, even after thorough psychiatric scrutiny by a staff closely attuned to the competency issue and strongly favoring the return of the mentally disturbed offender to the court, the percentage of individuals committed as incompetent (25 percent) seems rather high compared with other reports in the literature, which cite figures from 14 percent to as low as four percent in some jurisdictions (8, 17). Whether this is a result of a greater preponderance of severe psychopathology in the population our clinic serves than in that of other jurisdictions,[2] a result of more selective and appropriate referral of defendants for competency evaluation, or a result of other factors has not been established. Amid the complexities of our imperfect legal system and the imperfect science of psychiatry, we can be cheered somewhat by the fact that we are certainly serving the best interests of the mentally ill offender and of justice in the broadest sense when we return the competent defendant promptly to the court.

[2] The Forensic Psychiatry Clinic of the New York City Criminal Court is responsible for performing competency (fitness) examinations on all defendants who appear before the Manhattan Criminal Court in any case in which the court questions the defendant's competency at any time from arraignment to sentencing. Either the judge or one of the attorneys may raise this question, whereupon the judge issues a court order for an examination.

The number of arraignments made before the Manhattan Criminal Court each year is staggering. In 1967–1968, 110,413 arraignments were handled by the court. A minuscule proportion of these cases (601) were referred for competency screening. In the first five months of 1972—the year this paper was written—38,841 arraignments had been brought before the court and 338 of these cases were referred for competency (now fitness) evaluation—a mere 0.87 percent of the total number of arraignments.

Designing an Experientially Based Continuing Education Program

BY WILLIAM H. BARBER, PH.D., AND HUGH JAMES LURIE, M.D.

Based on their experience in leading continuing education workshops for various mental health workers, the authors recommend the use of experiential learning techniques in such programs to accomplish attitude change, personal involvement, and the development of specific clinical skills. The authors outline elements of design that they feel to be essential to all such training programs, including techniques used in sensitivity groups, and present examples of two possible workshop formats.

EXPERIENTIAL LEARNING METHODS have been increasingly employed to train mental health personnel ever since the beginning of sensitivity training programs in the late 1940s under the auspices of the National Training Laboratories Institute for Applied Behavioral Science (1). Many of these techniques and their uses in particular programs have been described (2), but the precise ways in which attitudinal change is brought about and specific skills are developed in these programs have not been elucidated.

This paper will attempt to describe the aspects of program design that we feel promote: 1) active participation and learning, 2) an examination by participants of their own attitudes toward the material, and 3) achievement of specific behavioral objectives.

BACKGROUND

Increased awareness of mental health problems and of manpower limitations in dealing with them have combined to focus attention on the need for effective preservice and inservice training of personnel in health and mental health fields. This need has led to the development of the Manpower Training Division in the National Institute of Mental Health (3) and to the inauguration of many programs at state and local levels aimed at training mental health workers from many disciplines and retraining existing personnel to help solve mental health problems.

Dr. Barber is Professor, Department of Psychology, Eastern Washington State College, Cheney, Wash. 99004. Dr. Lurie is Coordinator, Continuing Education Program in Psychiatry, Department of Psychiatry, University of Washington School of Medicine, Seattle, Wash.

This work was supported in part by Public Health Service grant MH-11984 from the National Institute of Mental Health.

The authors wish to thank Ms. Margit W. Gerow, University of Washington, for her help.

In such training programs, emphasis is naturally placed on the acquisition of information and a general ability to utilize such information. It has become apparent, however, that attitudinal change and the development of specific mental health skills are equally crucial for the effective training of mental health workers.

PROBLEMS

There are many problems connected with experiential learning. The multiplicity of "experiences" currently available—ranging from nude marathons to highly structured sensitivity sessions or communication workshops—and the many disparate labels and terms that have been attached to particular approaches within the human potential movement make it difficult for anyone but a sophisticated student of the whole movement to distinguish the nuances of similarity or difference among the "schools." Another problem is the lack of specified objectives and predictable outcomes related to particular kinds of group activities. This seems to be due to the relative paucity of validating research (4). In addition, a certain notoriety has become associated with some of the groups within the movement (e.g., nude groups), and this has been accompanied by some suspiciousness and skepticism among the more conservative elements of the mental health community about the movement in general (5).

In planning and implementing courses to increase the expertise of mental health personnel, we believe that we have developed programs that impart information and effect attitude change while also promoting specific interpersonal skills—all in a relatively predictable way. These programs use an experiential learning format that incorporates many of the principles and practices of sensitivity sessions. The elements of design included are felt to lead to attitude change, cognitive awareness, and skill development while also capturing the sense of achievement, closeness, and heightened self-awareness for which the sensitivity groups are, ideally, noted.

CONTEXT AND SETTING

The authors have been associated with workshops in the West (Washington, California, and Oregon) and in the Southeast (Alabama). Participants have included psychiatrists, nonpsychiatric physicians, nurses, doctors' wives, volunteers from mental health agencies, high school and grade school counselors, social workers, and other mental health professionals and paraprofessionals.

The workshops have been organized around varying topics: psychiatry for the nonpsychiatric physician, parent-adolescent relationships, family therapy techniques, seminars on death and dying, and increasing interpersonal skills.

The expectations of the participants in such workshops appear to be varied: some expect a "teacher" to give a didactic, directive presentation of facts; others—those having some experience with new learning models—show interest in experiential techniques as a way of gaining new skills and looking at their own attitudes; and some frankly anticipate being magically "turned on" by a charismatic leader. Participants who approach the workshops with great skepticism or distrust are sometimes unable to unwind, especially during a relatively short session.

For the most part our workshops have been small, with 15 to 40 participants; on one occasion, however, these same techniques were applied to a group of 3,000 participants.

DESIGN OBJECTIVES AND METHODOLOGY

Gibb classified human awareness experiences on a continuum ranging from "personal growth" to "discussion-instructional" (5). The point on this continuum stressed during a particular program will depend not only on the amount of time available (an evening, two days) and the makeup and probable expectations of the group, but also on the subject matter of the workshop. In our workshops we attempted to find positions along this therapeutic-instructional continuum that met specified goals and at the same time provided an opportunity for personal emotional involvement by the participants.

After experimenting with various formats we have isolated several factors that we feel to be crucial in the design of all programs. These include the following:

1. Face validity. Experiential learning exercises must have high face validity; the content of the task must be seen as real by the participants, but not so critical in their lives that the amount of anxiety provoked in discussing the topic cannot easily and quickly be dealt with. The role assumed by the participant must also be actually or potentially vital to either his personal or professional life.

2. Here-and-now focus. Though a workshop topic is usually announced in advance, the primary data used—feelings, attitudes, perceptions—are generated during the session by the participants through their experiences with one another. These data may be examined as subjects in themselves or as they relate to the topic of the workshop.

3. Active involvement. Every participant in a workshop has an active role. This may include an evaluative or observing role, but it is impossible for the participant to avoid being involved in the experience. In this way, some amount of affect is almost invariably mobilized within each participant.

4. Cognitive maps. At the beginning of the workshop a conceptual framework, usually in written form, is provided the participants to help them understand the exercise. This map serves to reduce their anxiety and allows them to evaluate their own performance and their feelings about it during the exercise. Other cognitive maps are developed after the experience, through group discussion and comparison of personal reactions. In this way the experience can be internalized, generalized, and rendered applicable back home.

5. Low ambiguity. Instructions that are clear, simple, and to the point are crucial to the overall success of the program. Emotional and intellectual ambiguity are also minimized by imposition of specific time limits, so that it is always clear that any given exercise is indeed an exercise—to increase personal and professional interpersonal competencies rather than to cope with existential anxiety.

6. Preliminary information. If the objective of the workshop is to develop competencies in dealing with particular clinical issues (such as death or dying, handling a hostile patient, etc.), adequate background information of a specific clinical nature must be provided before each exercise—either in the form of written information, spoken information from the leader, or a provocative videotape. These data keep the focus on the specific issue, allowing participants to examine their own skills, attitudes, and competencies in relation to the issue. The more specific the clinical skill to be scrutinized, the more specific the kind of information that must be provided.

ILLUSTRATIONS

The following examples will attempt to show how learning experiences were designed by us either to develop general interpersonal competence or specific skills and attitudes. For the latter purpose, a much higher degree of structure was imposed on the exercise, and the leader took care to point out the specific clinical relevance of the exercise for participants. For the development of general interviewing skills, less structure was imposed.

A Highly Structured Exercise

A group of approximately 20 physicians, psychiatrists, spouses, and miscellaneous participants met for a weekend workshop devoted to experiential teaching techniques for use with a dying patient. The workshop began with a brief didactic session on death and dying, using the developmental stages of dying patients described by Kübler-Ross (6) as a cognitive base. The workshop participants were then instructed to divide into groups of three, with each member to role-play a doctor, a dying patient, or an observer. After choosing roles the participants were shown a short videotape of a doctor interviewing a dying patient. The doctor tells the patient that he has leukemia, and the patient responds with denial and disbelief. The groups of three were asked to continue the scenario begun on the videotape. The observer was instructed to note the aspects of the interview that appeared to increase the patient's degree of comfort and the parts of the dialogue during which the doctor became uncom-

fortable or anxious and then to evaluate the overall effectiveness of the interview.

After ten minutes the simulated interview was stopped, a few minutes were allowed for feedback from the patient and the observer about the interview, and roles were then reversed, with each member of the trio getting a chance to play a new role. After everyone in each trio had had a chance to play all roles, there was general discussion and a short break. A further segment of the same videotape followed, showing a subsequent stage of the dying patient's course—again followed by role playing, feedback, role change, and general discussion.

This format was used throughout the entire session on death and dying, except for a short period when the group became immobilized by the helpless and hopeless attitude of the patient on the videotape; they were then allowed to see how the physician on the tape did manage to deal with his highly depressed patient.

Feedback about the design of this workshop was in general extremely favorable. Many participants felt that they had learned a great deal about how they came across to their dying patients. Physician participants particularly remarked that when they themselves had to play the dying patient they became more aware of the effect of their interventions.

In this exercise professional roles were clearly delineated, time limitations were definitely imposed so that the participants would not become too uncomfortable in the interviewing experience, and a cognitive framework was provided by use of the Kübler-Ross book and the videotape.

A Less Structured Format

Approximately 30 physicians and nurses, many of whom did not know each other, met for a one-day session designed to improve their basic interpersonal skills in working with patients—generally in office practice.

Part of the workshop was designed to improve general interviewing techniques. The group was divided into subgroups of three; each person in turn took the role of consultee, consultant, and observer. The consultee was asked to share a problem with the consultant—to explain it, answer questions about it, and trust the consultant to understand. The consultant was asked to listen to the consultee, to paraphrase, clarify, and summarize the information he was receiving, and to ask questions that showed his acceptance of the consultee. The observer was requested to be timekeeper, to coordinate role changes, and to take notes during the consultation and at its conclusion share his observations as to what was and what was not helpful about it.

Requirements for this exercise included a fairly strict adherence to time limits, an insistence on the problem being a "real" problem, some preliminary exercises to help the participants feel comfortable in a situation involving personal data, and repeated emphasis by the leader on the universal need for help, so that the exercise would be applicable both for professional roles and in the participant's personal life.

DISCUSSION

Training experiences that have as their objective enabling learners to *do something differently* after the experience require behavioral tryouts, feedback, and "re-try," accompanied by internalization. Some of the elements of design for such experiential programs have been delineated in this paper.

Subjective evaluation of some of the workshops thus structured has yielded interesting observations. Particularly for interprofessional groups and for groups in which there was a high level of anxiety, the elements of design listed above seemed to foster a feeling of closeness among the participants and a sense of mastery that many of them had seldom experienced in a teaching setting. In a significant number of cases participants could view their emotions somewhat objectively as they experienced them; this led to personal insights that could be transferred to professional settings.

We hope that further experimentation with this model and more precise evaluation of its long-term impact on attitude change will lead to successful training programs for professionals and paraprofessionals working in the sensitive field of mental health care.

The Requirements of a Psychiatric Residency Program Circa 1972

BY HARVEY LANGEE, M.D., IRA D. GLICK, M.D., BROWNING HOFFMAN, M.D., LARRY B. SILVER, M.D., AND ANDREW P. MORRISON, M.D.

This paper outlines the consensus of a group of career teachers of psychiatry on the elements of a training program that will produce a professional with competence not only as a physician but in the many other roles a psychiatrist must perform. The group arranged the elements into three headings: what a psychiatric resident needs to know, what he should be able to do, and the characteristics he should develop in the course of his training.

DURING THE FIFTH ANNUAL MEETING of the Association for Academic Psychiatry (AAP), an examination of the programs of psychiatric residency training in the U.S.—their goals, methods, and effectiveness—was begun. The AAP is composed of present and former recipients of the Career Teacher Award of the National Institute of Mental Health. The task of examining the residency programs was of special interest to the AAP since, as career teachers, its members were identified as individuals with a particular interest in and aptitude for the teaching of psychiatry.

The examination was prompted by the career teachers' concern about residency training as a major area of their own responsibility. Some of their questions were: What are the components of a "good" residency program? How can one be more effective as a supervisor? What are the points of view of different training institutions?

Beyond the questions of technique and orientation they saw a number of pressing reasons for a focused examination of residency training. These included the recent dramatic shift in the concept of psychiatric services to the population and the development of other professional and paraprofessional groups with skills previously reserved to the psychiatrist.

There was also an acknowledgment that perhaps residency training primarily for a private practice model of individual psychotherapy may be less than optimum for a profession whose members are increasingly found in salaried positions, in administration, and in teaching and consultative roles. Further, the scope of psychiatric knowledge has broadened substantially in the past decade.

When consideration was given to the requirements of residency training programs, it became apparent that effective examination of such training must begin by examination of the end product. What is a psychiatrist now, and what should he be in the next decade? What are the unique reasons for his existence as a distinct, visible, and highly paid professional?

The task of developing a "job description" of the psychiatrist is complicated by the mystique that is still associated with membership in this profession. This mystique has been dramatized for the public and appears to have been accepted by some psychiatrists and related professionals as well. As a result, certain reactions to the mystique have occurred. The group agreed that a mystique orientation, either pro or con, is more characteristic of professional adolescence than the state of mature wisdom that by now the profession as a whole has achieved.

Of course there are intangibles in the role of the psychiatrist—a role that embodies some of the priestly function found in most societies. This indeed is one element of a job description, but to outline a training program it is necessary to define as precisely as possible all the multiple roles a psychiatrist must fulfill.

The first of these roles is that of a physician, with his ultimate responsibility for life-and-death decisions and his guiding principle of *primum non nocere*. Also, as a physician the psychiatrist is uniquely able when he considers behavior to integrate the whole spectrum of factors influencing the human organism.

The combination of these two unique areas—life-and-death responsibility and wide-spectrum knowledge—should provide a certain affective orientation to other persons. While incapable of precise definition, this orientation should find its expression in a combination of empathy and objectivity in a clinical setting.

Beyond this central role as a physician, there are a number of other roles that would aid in the job description of the psychiatrist:

He is a student of human functioning.

He is a modifier of human behavior and has a variety of methods available for this purpose.

He is an individual with certain personal capacities, among them a tolerance for ambiguity, the ability to forestall premature closure, the ability to maintain simul-

This paper represents a summary of the deliberations of the 25 participants of the fifth annual meeting of the Association for Academic Psychiatry, North Andover, Mass., October 7–9, 1971.

Dr. Langee is Assistant Professor of Psychiatry, University of Florida Medical Center, Gainesville, Fla.; Dr. Glick is Associate Clinical Professor of Psychiatry, University of California, San Francisco, Calif. 94143; Dr. Hoffman is Assistant Professor of Psychiatry and the Law, University of Virginia School of Medicine, Charlottesville, Va.; Dr. Silver is Associate Professor of Psychiatry, Rutgers Medical School, New Brunswick, N.J.; and Dr. Morrison is Assistant Professor of Psychiatry, Tufts-New England Medical Center, Boston, Mass. Address reprint requests to Dr. Glick.

taneous distance and closeness to others, a degree of self-awareness, and, ideally, the capacity for change.

What, then, are the elements of a training program that would produce the professional described above? The career teachers believed that those elements could be arranged into three major headings—what the resident should know, what he should be able to do, and what he should be as a person.

WHAT THE RESIDENT NEEDS TO KNOW

1. The resident should be familiar with many theories of individual psychological personality development so that his knowledge has a broad eclectic base, and he must have an in-depth knowledge of at least one model for clinical application.
2. He should know the biological determinants of behavior and emotion. These would include relevant information from genetics, biochemistry, neurophysiology, neuroanatomy, and medical neurology.
3. He should know how to diagnose patients according to a descriptive nosology and relate this to a theory of psychopathology. To do this he will have to develop observational skills and the ability to use his own feelings as a diagnostic tool.
4. He should know the family, social, and cultural determinants of behavior. He should know how an individual interacts in a one-to-one setting as well as in larger social units. He should know theories of group and family dynamics.
5. He should know how to think critically. He must be able to evaluate the literature and to understand the fundamentals of research methodology.

WHAT THE RESIDENT SHOULD BE ABLE TO DO

1. The resident should be able to use the somatic therapies, including ECT and psychopharmacological agents.
2. He should know how to practice the various psychotherapies. He should be skilled in the forms of individual therapy in current practice that have some validity, and should be able to apply this skill to individuals and also to work with larger social units. Training in individual therapy is essential; training in group therapy, family therapy, and behavior modification is desirable.
3. He should know the concepts and practices of community psychiatry, including consultative techniques and aspects of preventive psychiatry.
4. He should have the tools and motivation for continuing his own education after training.
5. He should be familiar with diagnostic and therapeutic techniques with children and adolescents.

The areas just listed should be covered in the first two years of a residency program. The third year should be elective with opportunities for further training in such areas as teaching; community mental health; child, adolescent, forensic, and administrative psychiatry; research; psychoanalysis; student mental health; psychopharmacology; inpatient care; etc.

THE CHARACTERISTICS HE SHOULD DEVELOP

From this program the resident should be able to develop certain personal and professional characteristics. He should be able to:

1. Tailor the medical model to fit psychiatric objectives. That is, where the medical model tends to deemphasize emotion in the doctor-patient interaction, the psychiatric model encourages the use of emotion for diagnosis and treatment.
2. Accept a variety of values and behaviors in his patients and see them within their own social context.
3. Treat in his own style from a variety of models rather than "pouring into a mold." He should have developed or enhanced his capacity to interact, introspect, reflect, act, and be creative. He should have been able to achieve a change in his own personal growth in the course of his residency. This might have been done through psychotherapy but could also have occurred through supervisory relationships and feedback from other staff.
4. Reaffirm his own dignity as an individual through his training program.

In one sense much of the above can be looked upon as a pious statement akin to being against sin and for motherhood. On the other hand, there is a continuing need to establish the parameters of the psychiatric profession. How does the individual residency program serve present needs? How appropriate are the components of the examinations that lead to Board certification of psychiatrists? It is hoped that the statements herein may provide a basis for discussion of individual residency programs and the relationship of these programs to the task for which training takes place.

The Clinical Case Conference Reconsidered

BY J. REGIS MCNAMARA, PH.D.

The author questions the effectiveness of the case conference, a procedure that is widely used in mental hospitals. He suggests modifications in the conduct of the conference that involve telling the group about the amount of time, effort, and money expended on cases each session. He also proposes an alternative to the case conference that is based on the "critical paths" approach to time and resource management.

INCREASING ATTENTION has been directed toward institutional practices that negatively affect the behavior of the people the institution attempts to serve (1). However, the institutional practices that are a source of concern for the professional staff have been less well studied and understood. One such practice, steeped in the tradition of mental health institutions, is the clinical case conference. Although their exact nature will depend on the specific needs of the institution in which they are held, most case conferences share several common features. First, they are held at fairly regular intervals and are usually attended by a large number of interdisciplinary staff members. Second, the serial presentation of single cases is the focus of concern. Finally, the method of approach involves interdisciplinary data presentation, discussion, and debate followed by diagnostic decision making with or without treatment recommendations.

Although this type of approach has the merit of bringing different points of view to bear on a clinical case, its disadvantages tend to outweigh whatever collective merit the meeting of minds appears to offer. Two of the most outstanding deficiencies noted in this approach are its limited information-cost ratio and its questionable educational value for students and staff alike. Anyone who has ever had to sit through a case conference and listen to what appears to be the never-ending stream of data, debate, and philosophy that is meted out must have thought at one time or another, "What am I doing here?" or "Why should my students have to sit through this?" All too frequently the exchange of ideas about the case turns into a clash of ideas about man and his modus operandi in the world according to Freud, Rogers, or Skinner. Students and staff alike come away from such conferences with their stereotypes of other disciplines all the more reinforced because one discipline failed to recognize the importance of another's "paradigm" in dealing with the case (2). Given this state of affairs, what can be done to improve the nature of the case conference for the individuals involved?

Dr. McNamara is Assistant Professor, Department of Psychology, Ohio University, Athens, Ohio 45701.

ALTERNATIVES

A number of alternatives to the case conference method should be considered, if not actually tried. First, an attempt should be made to make the case conference shorter in length and more problem-oriented. This could be accomplished by means of simple group monitoring and information feedback. In its most elementary form this procedure would involve having the recording secretary start a stopwatch at the beginning of each case and stop it at the point where a collective decision was reached. This information could then be plotted on a graph in the conference room. At the beginning of each subsequent session the chairman could draw attention to the chart on the wall and the length of time the previous session had taken. A variation of this procedure would be to have individual members' contribution times recorded, plotted, and announced in addition to the group times. Both of the aforementioned procedures are predicated on the principle that observation will have a reactive effect on the individuals who are being monitored and will set the occasion for behavior change for these individuals (3).

A more complex way to make individuals aware of the amount of effort continuously being expended on a case would be to have a machine print out the dollars it is costing (prorated on each member's salary) per unit of time that the case conference is in session. After each session these sheets could be posted on the conference room wall and at subsequent sessions the chairman could announce the number of dollars paid to staff members during the previous conference. This is not unrealistic because it has been demonstrated that dysfunctional behavior improves as a result of having monitored records made public and subject to freely occurring environmental consequences (4, 5).

A more drastic way to modify the case conference is to use it in a more adaptive fashion. It is envisioned that a more adaptive case conference could evolve out of new ways by which disciplines relate to one another. For instance, departments could have their own internal organization with regard to both assessment and treatment, with limited extramural contact points between themselves and other departments. In this type of setting, departments that are responsible for assessment and treatment would generate critical intradisciplinary treatment paths according to models now used in business and in-

dustry (6, 7). These treatment paths would be generated independently by psychology, social work, psychiatry, and other disciplines, and would involve the step-by-step charting of the resources and treatment approaches available to that discipline as they are applied in a program of positive behavior change. These charts would then be fed into a computer or be subjected to clerical analysis; mutual collaboration between disciplines would occur only at points where treatment paths intersected with one another.

Intersections might occur under a number of different circumstances. For instance, people from two different disciplines may want to use the same method of treatment with a patient. This situation might occur when psychologists and psychiatrists both want to use electromyogram biofeedback to control muscle tension that the patient has experienced in a certain situation. They would meet and decide which discipline could most effectively administer that form of treatment under the particular circumstances. A different situation might occur if there were an intersection of two or more treatment paths that interfered with one another. If, in a program whose orientation was learning theory, the issue involved drugs and an intersection of treatment pathways occurred, then the psychologist and psychiatrist (one would hope in consultation with a clinical pharmacologist) would meet to resolve only this issue. It is envisioned that if the professional staff adopted such a system they would function at more effective levels both within their own profession and in interdisciplinary endeavors. This is because most of the professional activity in such a system would be directed toward solving problems of a manageable nature instead of reducing dissonance (8) or improving professional perception (9).

Such a system would also provide for program assessment and would allow continuous correction of procedure to increase the discipline's effectiveness in changing behavior. This would follow because once the steps in each critical treatment path for an individual are operationally defined, each health program's efficiency and effectiveness could be easily calculated on the basis of terminal outcome measures of performance (10, 11). "Track records" for each of the disciplines could then be established for different kinds of target problems in different populations. This information could be returned to the system for future reference in resolving interdisciplinary path intersections. An empirical approach like this would certainly be an improvement over the present kind of system, which usually involves little more than resolving superordinate-subordinate power relationships between disciplines.

CONCLUSIONS

The types of recommendations I have made for the case conference are only a few of the possible alternatives that could be used to influence the deeply entrenched organizational behavior of mental health institutions. The best use of the case conference and other institutional practices can be made only if an operations-research model is used in the absence of an empirical support base to test the assumptions and practices that are perpetuated. The case conference, like other behaviors we engage in, may only serve ritualistic needs that are neither functional or necessary for the well-being of staff or patients. We will never know, however, unless the character of the case conference is scrutinized and innovative alternatives are explored.

Rapid Control of Psychotic Excitement States with Intramuscular Haloperidol

BY FRANCINE SANGIOVANNI, M.D., MICHAEL A. TAYLOR, M.D., RICHARD ABRAMS, M.D., AND PEDRO GAZTANAGA, M.D.

The authors conducted an open clinical trial of high doses of parenteral haloperidol in the treatment of 40 acutely excited psychotic inpatients. Their preliminary results suggest that intramuscular haloperidol in doses up to 60 mg. a day is safe, effective, and well tolerated in the management of such patients. Adverse reactions, which were infrequent, included extrapyramidal symptoms, lethargy, and, in one patient, transient hypotension.

THE MANAGEMENT of acutely excited, combative, or agitated psychotic patients on general psychiatric wards is frequently accomplished through the use of parenteral medication. Chlorpromazine is widely used for this purpose, its main limitation being that it sometimes causes hypotension. Oldham and Bott (1) recently found haloperidol (a nonphenothiazine neuroleptic) to be effective and safe in controlling acute excitement states. In view of their results, we undertook an open clinical trial of high-dosage parenteral haloperidol in acutely excited patients.

METHOD

We treated acutely excited patients whose aggressive, overactive, or assaultive behavior could not be controlled by persuasion, seclusion, or parenteral sodium amobarbital (250–500 mg. intramuscularly every four hours). Patients received an initial intramuscular injection of 10 to 30 mg. of haloperidol; the dosage varied with the patient's age, weight, and severity of illness. The dose and frequency of subsequent injections were decided clinically on the basis of the therapeutic response or the development of adverse side effects. Haloperidol injections were given one to three times daily; when adequate behavioral control was achieved, oral medication was instituted.

We evaluated each patient frequently throughout the day for clinical response or for the appearance of unwanted secondary effects. Blood pressure was measured 30 and 60 minutes after the initial injection; a fall in systolic pressure of 20mm.Hg or more below baseline or to a level below 100mm.Hg was recorded as clinically significant. Medication for parkinsonian symptoms was administered when clinically indicated, but never prophylactically.

The authors are with the Department of Psychiatry, New York Medical College-Metropolitan Hospital Center, 1901 First Ave., New York, N.Y. 10029, where Dr. SanGiovanni is a resident, Drs. Taylor and Abrams are Assistant Professors, and Dr. Gaztanaga is a Fellow.

RESULTS

We treated 40 patients, ranging in age from 22 to 69 years (mean = 38 years). There were 22 women and 18 men. Diagnoses included manic-depressive illness, manic type (N = 32); paranoid schizophrenia (N = 2); suspected seizure disorder (N = 3); and organic syndrome (N = 3). The total 24-hour dosage ranged from ten to 60 mg. of haloperidol.

Improvement was rated clinically and categorized as absent, minimal, moderate, or marked (a designation that included complete recovery). As seen in table 1, moderate to marked clinical improvement occurred in 90 percent of the patients within 72 hours. There was no difference between men and women in the eventual control of symptoms (i.e., at the end of 72 hours), but table 2 shows that during the first 24 hours 73 percent of the women responded with moderate or marked improvement, compared with 44 percent of the men ($\chi^2 = 3.29$; $df = 1$; $0.05 < p < 0.10$).

Table 3 shows the total dose of haloperidol required to control the excited behavior (patients who had displayed such behavior showed moderate to marked improvement). Women responded to lower doses of medication than men; 50 percent reached control at a total dose of less than 30 mg., compared with only 17 percent of the men ($\chi^2 = 5.06$; $df = 1$; $p < 0.025$).

Of 18 patients who received an initial injection of 20 to

TABLE 1
Clinical Response to Intramuscular Haloperidol Over 72 Hours

Response	Men		Women		Total	
	Number	Percent	Number	Percent	Number	Percent
Minimal improvement	3	16	1	5	4	10
Moderate improvement	1	6	2	9	3	8
Marked improvement	14	78	19	86	33	82
Total	18		22		40	

TABLE 2
Time Taken to Control Excitement with Intramuscular Haloperidol

Period	Patients Controlled Each 24 Hours (Cumulative)					
	Men		Women		Total	
	Number	Percent	Number	Percent	Number	Percent
24 hours	8	44	16	73	24	60
48 hours	14	78	20	91	34	85
72 hours	15	83	21	95	36	90

30 mg. of haloperidol, 11 showed moderate to marked improvement within 24 hours; all but one were transferred to an oral medication regimen. Of these patients, three had relapses over the second 24-hour period and required an additional day of parenteral medication for a sustained response.

The most frequently encountered side effect was mild to moderate lethargy, which lasted several hours after the injection. This occurred in 35 percent of the patients and almost always during the first day of treatment. A parkinsonian syndrome developed in six patients (four men, two women), each of whom had received medication for more than 24 hours, at a total dose of at least 60 mg. of haloperidol. We also observed that five of these six patients developed this syndrome while receiving injections of haloperidol at the lower single-dose range (15 mg.). The isolated acute dystonic reactions that occurred in four other patients were rapidly relieved by parenteral antiparkinson agents. Coarse hand tremor alone occurred in five additional patients (two men, three women), each receiving 15 mg. injections.

One 27-year-old man had a transient 20 mm.Hg drop in systolic blood pressure after his first 30 mg. injection of haloperidol. There were no observable symptoms from this blood pressure change, and his excitement diminished without the need for further parenteral haloperidol.

TABLE 3
Total Dosage of Intramuscular Haloperidol Required to Control Excitement

Dosage	Men		Women		Total	
	Number	Percent	Number	Percent	Number	Percent
Less than 30 mg.	3	17	11	50	14	35
30–60 mg.	7	39	7	32	14	35
More than 60 mg.	5	28	3	14	8	20
Uncontrolled	3	17	1	5	4	10
Total	18		22		40	

DISCUSSION

Our preliminary results confirm the safety and effectiveness of parenteral haloperidol in daily doses up to 60 mg. for the initial treatment of acutely excited patients. Women appear to respond more rapidly and at lower doses than men, a finding similar to that of Oldham and Bott (1). Ritter and associates (2) recently gave five mg. of haloperidol intramuscularly every six to eight hours and noted moderate to marked improvement in 68 percent of their patients within 48 hours. Our experience suggests that higher dosage haloperidol may yield more rapid and effective control of excitement. This difference may also derive from patient selection, for Ritter and colleagues (2) treated only men.

We observed that the majority of extrapyramidal reactions occurred in patients receiving injections of haloperidol at the lower dosage range (less than 20 mg.); this is consonant with the inverse relation between dosage and extrapyramidal symptoms that has been reported for fluphenazine (3).

We recorded a single episode of hypotension, a low frequency that is similar to the finding of Ritter and associates (2), who found no postural hypotension in their sample, and of Sainsbury (4), who gave as much as 90 mg. of parenteral haloperidol each day to patients with delirium tremens without the development of hypotension. Oldham and Bott (1) reported a somewhat greater incidence of hypotension; four percent of their patients showed a fall in systolic blood pressure below 100 mm. Hg, and 11 percent showed a drop of 20mm.Hg below baseline.

Finally, the nursing staff noted that no patient complained of pain at the injection site, in spite of the large volume of solution (2–4 cc.).

Referral Failures: A One-Year Follow-Up

BY WALTER A. CHAMEIDES, M.D., AND JOE YAMAMOTO, M.D.

The authors found that most of the patients in their study—98 out of 153—did not make or keep their appointments at an outpatient clinic after being evaluated and referred. One year later they were able to obtain information on 51 of these patients and found that 40 of them had received some type of professional care.

WHAT HAPPENS to our patients who are referred but fail to follow through with their appointment is an issue that has bothered us at the outpatient clinic of the Los Angeles County-University of Southern California Medical Center. Many of our patients are referred by our psychiatric evaluation-admitting area, which functions as a 24-hour crisis center. This study was an attempt to determine what had happened, after one year, to patients not completing the referral.

Hyman and Schneidman (1) reviewed the records of the 1,265 patients seen in the evaluation area during one month and reported that 153 were referred to the center's outpatient clinic. (The rest were admitted or were referred to other community facilities, or else the crisis was resolved.) These 153 patients were divided into three categories: those who made no contact of any kind to make an appointment (80 patients, or 52 percent); those who phoned for an appointment but never showed up (18 patients, or 12 percent); and those who contacted the clinic and were seen (55 patients, or 36 percent). When they completed their study five months later, 37 of the 55 patients who came for their appointments were still in psychotherapy.

METHOD

The first two categories—the 80 patients who never contacted the clinic and the 18 patients who did but failed to keep their appointments—equal 64 percent of those referred to the center's outpatient clinic. An attempt to determine what happened to them was undertaken a year later, and three methods of information gathering were used. First, we reviewed the patient's chart. If there was no relevant information on the chart, we then telephoned the patient. Finally, if the patient had no phone, we then sent a letter with a questionnaire to be returned. The following are the results of our study one year after referral.

The authors are with the Department of Psychiatry, University of Southern California School of Medicine, 1237 North Mission Rd., Los Angeles, Calif. 90033, where Dr. Chameides is Assistant Clinical Professor and Dr. Yamamoto is Professor.

RESULTS

Of the 80 patients who were referred but did not call for an appointment, we were able to gather information on 38. Our data for these 38 patients were based on 15 hospital charts (three charts were unobtainable), 17 phone contacts (21 had phones), and six questionnaires (41 were mailed). Of these 38 patients, 30 had received some type of care. Fifteen had been in our clinic, nine in other community facilities, and six had been hospitalized. Thus, approximately one year after the original referral, 79 percent of the patients whom we were able to track down had received care.

These patients gave a variety of reasons for not making an appointment. Some denied being told to call; some said that the clinic was too far away; one felt that he got the runaround; one did not call for "fear of being a nut"; others said that they felt better and thus did not need an appointment.

Of the 18 patients who called for an appointment but, after four months, had not arrived, we were able to obtain information on 13. Our data for these 13 patients were based on two hospital records of our clinic patients (one chart was obtainable), six phone contacts (seven had phones), and five questionnaires (nine were mailed). We found that ten patients (77 percent) had received care. Two had been in our clinic, six in other community facilities, and two had been hospitalized.

These patients gave various reasons for not coming to our clinic. There was too long a waiting list; they were feeling better; it was too far to travel; or they did not remember making an appointment. One patient did not come because she discovered that she was pregnant. One stated that she did not keep her appointment because she was in the hospital having a baby at her appointment time. She described the evaluation area as being "like a scene from a 'B' movie . . . long wait . . . a more desperate patient could walk out without anyone helping them. . . . My thoughts may not be too accurate . . . like a bad dream." One patient canceled his apointment because he wanted to try to resolve his crisis on his own.

We also studied the possible effect of the professional role of the therapist who made the initial referral. We found that it made no difference whether the referring professional was a staff psychiatrist, psychiatric resident, or social worker.

In summary, we found that most of the patients in our study—98 out of 153—did not make or keep their ap-

pointments at our clinic after being evaluated and referred. One year later we were able to obtain information on 51 of these patients and found that 40 of them (78 percent) had received some type of professional help.

If we include those 55 patients who made and kept their initial appointments with those receiving professional help after one year, a total of 95 (or 62 percent) of the original 153 referrals received treatment. We were unable to locate 47 of the 153.

DISCUSSION

How are we to evaluate the findings? From our data one could say that continuity of care is not being given to many in this population (2). Another way of looking at these referral failures would be that they were unable to accept the care given to them. Many factors could determine this, including the type of precipitating stress, the social status of the patient, the manner in which patients in crisis are handled, the sex and age of the patient, the time of day patients are seen, and the waiting period for an appointment (3–5). It is of interest to note that Jacobson and associates (6) found that 26 percent of their patients did not return to their crisis treatment center after one visit, even though they were offered further treatment, with no waiting period, by the same therapist. Still, most of the patients whom we were able to locate did get some help during the one-year period. Those requiring hospitalization might be seen as referral failures. However, they may have needed inpatient care from the beginning, and this was accomplished.

One could say that it is reassuring to those of us in the mental health field that referred patients eventually get professional help. It is distressing, however, that our initial encounter with patients in a crisis does not more often lead to a rapid follow-through with resolution of their problems. Finally, it appears that some patients only need to be seen once and to know that help is available.

LETTERS TO THE EDITOR

Rapid Reversal of Tardive Dyskinesia

SIR: The literature on tardive dyskinesia has emphasized the irreversibility of this disorder, which is true in most instances. However, the syndrome may subside in younger individuals and in children (1). In an article published in this journal (2), I indicated that "symptoms . . . may . . . decrease or even disappear after several months off drugs." The case I wish to report here is of interest because tardive dyskinesia subsided in a matter of days after the withdrawal of all neuroleptic agents.

Case 1. Natalie L., a 41-year-old woman, was admitted to Spring Grove State Hospital in July 1972 with a diagnosis of schizophrenia. Although hospitalization was preceded by two and a half years of suspiciousness and withdrawal, she was never hospitalized or treated with psychotropic agents. During the first three or four months of hospitalization, therapy consisted of thiothixene, chlorpromazine, doxepin hydrochloride, and trihexyphenidyl hydrochloride. Although she improved, she continued to experience anxiety and a variety of somatic symptoms.

In November 1972 she was not found ready for discharge and was transferred to my service. When I first saw her, she presented a clinical picture suggestive of akathisia; therefore, the use of all drugs except for anticholinergics was stopped for two weeks. During this period all her symptoms became worse, so I prescribed chlorpromazine in a dosage of 200 to 400 mg. per day. This was later changed to 10 mg. of haloperidol per day, mainly because haloperidol appears to be better tolerated by patients with real or imaginary gastrointestinal disorder.

In April 1973 I suspected that none of the patient's symptoms was drug related; hence, I discontinued trihexyphenidyl hydrochloride. Two days later she complained of dysphagia and dyspnea, but these complaints were not accompanied by objective signs of dystonia. On the other hand, symptoms of parkinsonism were very conspicuous. The administration of haloperidol was discontinued, following which the parkinsonian syndrome cleared completely.

A day or two later, however, she manifested the following symptoms: rhythmical protrusion of the tongue, up-and-down movements of the chin, and mild choreoathetoid activity of the ankles. The clinical characteristics of the new syndrome, its appearance after drug withdrawal, the fact that parkinsonism preceded hypermotility, and finally, the complete absence of discomfort (in a hypochondriacal patient) were consistent with a diagnosis of tardive dyskinesia.

The abnormal motility in the oral region was observed for the first time not only by me, but also by the patient and the nursing personnel. All involuntary movements lasted for about ten days and then subsided, except for an occasional ticlike movement of the lips. Natalie, who was extremely self-conscious about her appearance and eager to report all her ailments in great detail, seemed to be completely unaware of any problem in her mouth or other parts of her body.

The question is, would the patient have developed persistent dyskinesia had I continued the administration of neuroleptics? She improved mentally and went home a few weeks later; I was therefore not confronted with the dilemma of exposing her to further chemotherapy. I feel, however, that patients who are very sensitive to the neurotoxic effects of neuroleptics should not receive such compounds regardless of their mental condition. Too many persons exhibit permanent and often disabling neurological manifestations because these disorders are recognized by accident and the use of neuroleptics is discontinued when it is too late.

Baltimore, Md.

Intellectual Impairment in Uremic Patients

SIR: The article "The Psychological Evaluation of Patients for a Kidney Transplant and Hemodialysis Program" by Drs. Greenberg, Davis, and Massey (March 1973 issue) leaves several points unclear. The reader is left with the impression that the organic intellectual deficits and decreased energy seen in uremic patients should be taken into account when planning for the instruction of the patient in hemodialysis technique and in planning other areas of the patient's adaptation to the dialysis experience.

Unfortunately, the authors do not mention the point in time during the patient's course when psychological testing was administered, nor do they mention whether testing was repeated after the patient had been adequately dialyzed. One suspects that testing was performed while the patient was uremic, prior to his acceptance into a dialysis-transplant program. These important points should, I believe, be put into proper perspective.

During the past year I have evaluated 18 patients who were accepted for in-center dialysis, and I have had frequent contact with them throughout their subsequent treatment. Together with Greenberg and associates and with Abram (1), I was aware of the "organic" deficits that these patients evidenced while uremic. Prior to dialysis, when the metabolic abnormalities of uremia were flagrant, the patients frequently felt "foggy." They had difficulty with thought, attention, concentration, and memory.

However, the change in mental status following several weeks of adequate dialysis for these patients is considerable. The "organicity" diminishes to a marked degree in almost every case, as measured by bedside mental status evaluations and observations of patients' activities. For the most part, patients are able to learn well (to the extent of returning to college in some cases) and are able to carry out those intellectual functions of which they were capable prior to their periods of severe uremia.

If one of the purposes of psychological assessment is to evaluate a patient's ability to learn dialysis procedures and to help

plan future life activities, these assessments should be made following an adequate initial course of dialysis. If judgments about a patient's intellectual impairment are based solely on assessments performed prior to treatment, these judgments may prematurely label the patient as intellectually impaired. The perceptions of the treating staff may be biased toward viewing the patient as more impaired and less capable of necessary self-responsibility than is actually the case. Since minimization of dependency and maximization of self-care are valued goals in the management of dialysis patients, premature judgments of "organicity" upon which long-term plans are based are to be avoided.

Certainly there is a need for a study in which repeated assessments are made before the relationship between intellectual impairment and chronic dialysis is clear.

REFERENCE

JOEL YAGER, M.D.
Los Angeles, Calif.

SIR: The article by Drs. Greenberg, Davis, and Massey contains some concepts that should not go uncorrected. The authors deal with "organicity" in uremia in terms of "cerebral organic loss" as if it were a fixed quantity somewhat parallel to intellectual impairment in mental deficiency. "Organicity" as seen in uremia refers to acute brain syndrome or delirium. This syndrome, well described by Engel and Romano (1), is one of potential reversibility with change in the state of metabolism of the brain cells. In uremia, because of defective removal of waste products there is interference with the function of these cells. Of paramount importance is the timing of psychological tests of cognitive function in patients with impaired renal function. Testing prior to hemodialysis, i.e., while the patient is uremic, will give entirely different results (poorer function) than testing during or immediately after hemodialysis (better function).

The statement "We found very little evidence of any gross emotional maladjustment in our patient sample" is a conclusion that requires substantiation by data, none of which is given. The experience of most, if not all, clinical investigators in this area makes this statement very much subject to question. In a report in this journal Abram and associates (2) found that the incidence of suicide among hemodialysis patients was between 100 and 400 times greater than that of the general population. In a more recent study by Reichsman and myself (3), which has not been widely read by people who work in the behavioral area because of its publication in a journal of internal medicine, there is a comprehensive report on the problems in the psychological adjustment of these patients. In another investigation that I conducted by nationwide questionnaire of 519 adult hemodialysis patients and transplant recipients (4), the data show a marked deterioration in sexual functioning of hemodialysis patients of both sexes and of male transplant recipients.

There are other problems of importance in the psychological testing of uremic patients that were not described by Drs. Greenberg, Davis, and Massey but which are worthy of mention. If testing is performed prior to making a firm commitment to the patient that he will be accepted into a program of treatment, it will tend to be seen by the patient as a means of evaluation to determine whether he lives or dies, whether he will be accepted or rejected. This is a factor that must affect the test results.

Lastly, these patients are often quite sick and therefore unable to engage in concentrated activity over a long period of time. The statement that "a large number of patients are not prepared for the fact that the testing will last a number of hours and will require their cooperation" is best responded to by saying that these patients should not be tested for a number of hours. Testing should be performed over a much shorter period of time.

NORMAN B. LEVY, M.D.
Brooklyn, N.Y.

Drs. Greenberg, Davis, and Massey Reply

SIR: We would like to thank Drs. Yager and Levy for their thoughtful comments and the chance it gives us to further clarify our paper. Basically the comments revolve about the issues of potential intellectual deficits and serious psychological disturbances in hemodialysis and kidney transplant candidates.

We are in agreement with the fact that the mental status of these patients appears most consistent with the hypothesis of organicity when the patients are uremic. For this reason the patients in our sample who required dialysis at the time of evaluation were tested as soon after they were dialyzed as possible. Every effort was made to ensure that we were seeing the patients in as nonuremic a state as possible. We were interested in obtaining data under optimal physical conditions. Further, although some of the patients required hours of evaluation, the evaluations were conducted during more than one session to minimize the effects of fatigue and prolonged activities. Nonetheless, as we noted, almost all of our patients exhibited behaviors consistent with some type of intellectual deficit. This does not mean that our patients as a group looked markedly organic; they did not. Further, our paper raised the possibility that the losses might be reversible.

We would conclude from the data that *most* of our candidates exhibited deficit to some degree and therefore indications of minimal deficit should not be interpreted as unusual or used as a differentiating negative sign in making prognostic judgments concerning future adaptation.

With regard to personality evaluation, our sample of patients did not show evidences of severe psychopathology. No clinical or psychological test indicators (e.g., Rorschach genetic levels, F + percent, and R + percent [1]) gave significant evidence of severe disturbance. As we stated, none of our candidates exhibited delusions, hallucinations, or thought disorders. None were judged to be schizophrenic or psychotic although they were certainly defensive and had difficulty modulating affect. We did not consider our patients to be demonstrating severe psychopathology because they were having some difficulty adjusting to a life-threatening situation.

Abram and associates (2) did indeed find in their survey that the incidence of suicide is significantly higher in hemodialysis

patients than in the population at large. They reported a one-percent incidence of clear suicide attempts in this population, which is about 100 times greater than that of the general population. Put in other terms, if you interviewed 100 hemodialysis patients you might expect one to be clearly suicidal. We conclude that although the incidence is higher in this group, suicidal behavior is still not "typical" of the average hemodialysis patient.

The survey of Abram and associates also concluded that approximately three percent of dialysis patients die as a result of not rigidly adhering to treatment regimen. Goldstein and Reznikoff (3) argued that this behavior should not be considered "suicidal." They demonstrated the tendency of the dialysis patient to adopt an external locus of control with the result that patients do not perceive their behavior as playing much of a role in what happens to them. Thus they tend to perceive following their regimen as not particularly relevant to treatment outcome. Relatedly, we stressed that appropriate preparation and referral information might be therapeutic in giving the patient the feeling that he too is playing an important and active part in the treatment process.

In sum, we must still conclude that although there are certainly indications of adaptational difficulties, the "typical" patient we observed did not break down as a result of the stress. This finding is consistent with Sand, Livingston, and Wright's finding (4) that their sample was free from "gross psychological disturbances" and Abram's statement (5) that "the patient's ability to adapt to and function in the near terminal stages of uremia is seemingly better than previously recognized."

Assessing Self-Assessment

SIR: As a practicing psychiatrist I share the concern of my colleagues for maintaining high professional and ethical standards. However, the "Questions of the Month" from APA's Self-Assessment Program published in your December 1972 issue represent another area of concern.

How do you test a psychiatrist's proficiency to treat patients? Surely the knowledge required to answer the two published questions correctly does *not* in any way indicate the doctor's skills as a therapist. In fact, I would question the judgment of a committee that would include these two questions in a psychiatric self-evaluation test. I would be interested in knowing whether this feeling is shared by a significant number of other psychiatrists.

MARIAN G. MALCOLM, M.D.
Tenafly, N.J.

SIR: This letter is in answer to a letter from President Talkington in January 1973 strongly requesting that I take a self-assessment examination in order to avoid unpleasant situations with the U.S. government and the American Psychiatric Association.

When I received the Association's first request for self-assessment my reaction was to wonder whether or not the persons making up the examinations would know the right questions to ask me. For example, how are they going to test me for general clinical ability and aptitude? Numerous papers have revealed that persons with certain aptitudes for dealing with emotional illnesses have better results than others, regardless of what their training might be. Since medicine is a mixture of alchemy and magic that results in what we speak of as "the art of medicine," I wonder how they are going to test my possession of that mysterious art.

I recently wrote a textbook on psychiatry (1) that is widely used today in the psychology departments of various colleges. In order to write this book I had to learn a great deal about computers. I wonder how many test questions in the Self-Assessment Program deal with computers and if the men making up the test really know what a ToTe computer is. How many questions would they be able to ask me about it?

I wonder how many questions in the Self-Assessment Program will deal with the field of cerebral allergies, which is a specialty that has interested me a great deal. In fact, I find it so important that I test all my patients for food allergies. One of my patients is sensitive to chocolate and sugar. He recently ate a candy bar and came into my office psychotic for the first time in many months. I wonder if the Self-Assessment Program will ask me how such a reaction should be treated.

I have also discovered that one-third of my patients have low serum B-12 levels. I wonder how many of the questions of the Self-Assessment Program will deal with the metabolism of vitamin B-12. For instance, where exactly is it used as a coenzyme and what are the neurological effects of its absence? Is the lack of vitamin B-12 best treated by injections of cyanocobalamin or hydroxycobalamin, or are the results better when these are combined with crude liver extract injections? Also, what about folic acid levels in these patients, how should serum folic deficiencies best be treated, and do these have an effect on the central nervous system?

Will the Self-Assessment Program ask how many physicians have their patients examined yearly to assess their body levels of such important minerals as calcium, magnesium, and zinc, all of which are intimately connected with neurochemical processes?

Perhaps most important of all, I wonder how the Self-Assessment Program will test my creativity and the creativity of the members of the American Psychiatric Association. American psychiatry is singularly lacking in creativity. There is much rehashing of old stews but the fact is that psychoanalysis, electroconvulsive therapy, and the use of tranquilizers have all been imported from Europe. I wonder whether an attempt will be made to correct this lack in the members or whether those members without creativity will simply be dismissed from the Association. I wonder if continuing self-assessment and relicensing procedures will attract creative people to our profession

or simply nauseate them and turn them toward other professions.

Lastly, I wonder how the assessors are going to test me for my ability to write. I spent a year at the New School for Social Research taking writing courses that I find very valuable, but I wonder exactly how much the assessors know about the techniques of creative writing.

It would seem to me that the American Psychiatric Association should spend its money fighting any legislative proposals for recertification rather than meekly going along with this bureaucratic trend and even assisting it. I suspect that the assessors are simply uncreative bureaucrats who secretly want to turn APA into one big Boy Scout troop whose members bathe every day and help old ladies across streets, receiving Brownie points for their good deeds.

Forgive me for sounding emotional. I do not ordinarily write letters such as this, especially since I am in the midst of another book and am up at 6:30 every morning to work on it. The problem is that the letter from Dr. Talkington was so repulsive to me that it was necessary for me to get my feelings off my chest.

I take it that psychologists, marriage counselors, gurus, self-appointed encounter group leaders, ministers, the neighborhood bartender, and all the other people who deal with psychiatric problems will also be examined and will receive certificates telling how many Brownie points they have been given throughout the year.

H. L. NEWBOLD, M.D.
New York, N.Y.

Dr. Carmichael Replies

SIR: Drs. Malcolm and Newbold base their objections to APA's Self-Assessment Program on what it has never professed to do. It was never intended, nor could it have even been conceived, that the program would effectively measure every aspect of a practicing psychiatrist's knowledge and skills. Could any program on any subject, medical or nonmedical, possibly test the universe of knowledge about *any* field?

What the program *does* profess to do is provide a reasonably accurate measure of the degree to which a practicing psychiatrist has retained knowledge of basic facts and skills in procedures he was once taught. In that respect, it serves an important function. Dr. Malcolm is correct in pointing out that individual skill in treating patients is not measurable. But we have not attempted to do that. Likewise, Dr. Newbold may well wonder whether the framers of the test will include questions about B-12 metabolism, but to include questions relevant to the special interests of every member of the Association is simply beyond comprehension.

In sum, then, I must reject these complaints as basically groundless. Let these physicians focus instead on whatever shortcomings they find in the Self-Assessment Program itself—not on how it fails to measure up to admittedly impossible comprehensiveness.

Washington, D.C.

Ataractic Drugs Versus ECT in Schizophrenia

SIR: In my opinion, Drs. Murillo and Exner, in their article "The Effects of Regressive ECT with Process Schizophrenics" (March 1973 issue), seriously compromise their findings by methodologic errors.

The area of greatest concern is their lack of specificity in reporting the drug therapy of their control group. They fail to specify the type and dosages of the ataractic drugs used. In my own experience and that of my colleagues at the Sacramento Medical Center, dosage is a critical factor; many schizophrenics do not respond to the usual recommended dosages.

In addition, we have been struck by the difference in response between the sedative and the nonsedative antipsychotic drugs. Nonsedative antipsychotics, in our opinion, lead to more prompt and complete remission of psychotic symptoms. Thus Drs. Murillo and Exner could indeed show that regressive ECT led to a more favorable response if they selected their ataractic drugs poorly and used them in small dosages.

JAMES SPENSLEY, M.D.
Sacramento, Calif.

Drs. Murillo and Exner Reply

SIR: In Dr. Spensley's communication there appear to be three issues, explicit or implicit, that require some comment. First, Dr. Spensley is quite correct in noting our failure to include the types of drugs used with our control group. Our own volume of correspondence points to the significance of this omission, which occurred primarily because of space limitations. Three different drugs were used with our controls: 11 patients received haloperidol (Haldol), six were treated with chlorpromazine (Thorazine), and four received a combination of trifluoperazine hydrochloride (Stelazine) and chlorpromazine. The selection of which drug should be used was left to the psychiatrist responsible for the individual patient.

The second issue raised by Dr. Spensley concerns dosage. As in the selection of drugs, the psychiatrist responsible for the patient made the decisions concerning dosage. In general, dosages were at, or higher than, recommended levels. Our decision to follow this procedure was based on two factors. First, we were not interested in testing for the effects of one single drug or specific dosage level. Rather, we were interested that our control group be treated under natural conditions wherein good medical judgment was displayed. Second, none of the five attending psychiatrists knew which patients were actually included in our study; data were collected on all of the patients in the hospital. To have interfered with the normal hospital routine could have "blown our cover" and our subjects might have been treated somehow differently than were other patients.

Finally, and possibly most important, is Dr. Spensley's implication that the patients treated with drugs did not improve. This is simply not true. All 21 of the controls manifested complete remission and were discharged from the hospital. The fact that the patients treated with regressive ECT were rated more favorably at discharge and seven to nine weeks thereafter does not mean that those treated with drugs were not "successful" cases. We are currently in the third year of an extensive follow-up of these subjects and find that the majority in each group continue to sustain the treatment gains. The relapse rate in each group has been low, and the behavioral ratings obtained have been generally quite reassuring.

We do not wish to imply by our data that regressive ECT

should now replace chemotherapy as *the* treatment for process schizophrenia, for that is clearly not a warranted conclusion. We do believe, however, that our work calls attention to another viable treatment modality that can be effective for some schizophrenic patients.

There obviously remain many unanswered questions about the how and why of regressive ECT. In fact, the mysteries of convulsive treatment plague us now as much as they have others in past decades. We feel that the potentials of the treatment method are quite favorable. However, substantially more investigation into the effects of the treatment—especially using some of the more sophisticated methods of neurology and biochemistry—as well as additional studies such as ours concerning the outcome of the treatment are required before definitive conclusions may be drawn.

No-Suicide Decisions: A Procedural Rule

SIR: The results reported with suicidal patients by Drs. Drye and Goulding and Ms. Goulding in "No-Suicide Decisions: Patient Monitoring of Suicidal Risk" (February 1973 issue) are impressive. This important contribution was nevertheless difficult to read; I had to keep rereading and referring back to clarify the procedures. This difficulty was partly a result of writing style and, more importantly, of the sequence of steps described.

Because the procedure looks as if it could be taught to various staff members in a reasonably reliable and effective way, I have devised a graphic "flow chart" that is actually an algorithm (procedural rule) allowing correct step-by-step decisions, even if one's memory is not perfect. Although it is impossible to reproduce the chart in this section of the *Journal*, copies of it are available from me on request at the address below.

I would like to recommend that more therapeutic procedures be presented in the form of a flow chart; it is a great help in developing the logic of a proposal. Why couldn't our income tax forms be set up in this way?

Incidentally, the authors of the article under discussion seem to use a transactional or decision-making orientation. Their procedure can also be understood as the gradual shaping of verbal and covert responses that seem to be incompatible with overt self-destructive behavior. A number of possible additional steps might be considered, such as gradually lengthening the time span of the decision.

ROSS GRUMET, M.D.
Director of Training and Research
Georgia Regional Hospital at Atlanta
3073 Panthersville Rd.
Decatur, Ga. 30034

Dr. Drye Replies

SIR: I think Dr. Grumet's suggestion of a flow sheet is interesting and potentially helpful. The flow sheet could have a variety of designs, as long as the arrows eventually get back to one of three points: 1) "I will not kill myself, no matter what, for a definite period of time." This is the safe position. 2) "I won't make such a statement." Patient requires supervision. 3) "I won't kill myself, if . . . ." This is a qualified position and further work is needed to reach point 1 or 2. As Dr. Grumet suggests, the time span portion is the easiest to work with and can be gradually lengthened.

This is certainly a transactional model, with a strong emphasis on the ability of both patient and evaluator to reach clear decisions. In this procedure, when the patient reaches conclusions incompatible with suicide, at least for a period of time, he may be considered safe for that period. I want to thank Dr. Grumet for his perceptive comments and suggestions.

ROBERT C. DRYE, M.D.
Carmel, Calif.

Broken Promises

SIR: Consider the following events. Between September 1971 and June 1973, a single U.S. Army installation lost four assigned psychiatrists to conscientious objection. All had been deferred under Berry Plan agreements and all declared conscientious objector status immediately prior to their conclusion of residency training and commencement of active duty.

While conscientious objection and changes in one's personal beliefs are acceptable, it would be a most curious coincidence that four men of the same medical specialty, bound by the same contract, should declare the same personal-legal status at identical times in their lives. That this should have occurred at a single location strongly suggests that this phenomenon is widespread.

In addition, I have been informed that recently several Berry Plan-deferred physicians successfully brought suit to avoid military service by alleging that their contracts constituted "forced enlistment" and were therefore not binding. Apparently, their feeling was that since the draft is now no longer operative, physicians should be exempt, despite the fact that they avoided active duty previously by promising to serve at the present time.

Indeed, it is difficult to imagine anyone entering a Berry Plan contract except to avoid being drafted as a generalist or at a risky period of time in one's career. Further, it has become a common belief that declaration as a conscientious objector is likely to be successful simply if one is a physician. The military appears to have been complicit in this by not contesting such cases.

I am by no means promoting military service for psychiatrists. The practice of third-rate medicine in the military is usually a frustrating, demoralizing, and unpleasant experience. What alarms me is the apparent facility with which a seemingly sizable number of psychiatrists are able to consider a contractual agreement void for reasons of personal convenience. It is difficult to interpret the above data otherwise. I hope this is not indicative of a general drift toward a lack of integrity within the profession.

BOOK REVIEWS

Psychiatry and Ethics, *by Maurice Levine, M.D. New York, George Braziller, 1972, 377 pages, $12.50.*

This is the second book and the posthumously published work of a dedicated, scholarly, respected, and warmly human colleague. Maury Levine was a man of the greatest personal and professional integrity, and his choice of the area of ethics in its broader aspects is most appropriate. His thoughtful and carefully written study following 40 years of work as a psychiatrist warrants the scrutiny of all in our field.

Part 1 includes ten succinct chapters concerning psychiatry and ethics, which the author developed from a series of six lectures given upon invitation from the Weil Institute in Cincinnati. Part 2 includes six selected papers by the author, plus ample notes and bibliography. There is an excellent introduction by Margaret Mead and a fine biographical note on the author by George L. Engel.

This book is *not* a study of the ethics of psychiatry or of its practitioners in their many avenues of professional activity. In some contrast, it presents a broad sampling of the ways in which psychiatry and related fields can contribute to the further development of ethical principles and ethical behavior. The value of a multidisciplinary approach to the constructive evolvement of ethics becomes increasingly evident.

The discussion of ethics, even in a broad context and in a psychiatric setting, could well become involved, pedantic, and/or dull. However, this is far from the case here. The author's approach is subtly easy and conversational in tone. Indeed, his style is almost deceptively simple, and the book's thought-provoking content seems at first misleadingly easy to absorb.

Noting that "a good part of a man's ethics consists of the ways in which he copes with his temptations," Levine opens by discussing the process of self-scrutiny, with its attendant hazards, pitfalls, and temptations, personally illustrating important points. The ethical parts of the personality are likely to be regarded approvingly and as positive, in contrast with certain hostile and sexual aspects.

According to Levine, the concept of a working alliance (as in the therapeutic situation) is of great importance in the development of ethical principles and behavior. In the pursuit of such developments and for the overall study, he defines ethics as referring to those patterns of individuals or groups that are relatively restrictive, limiting, or inhibiting of otherwise destructive impulses or behavior. He also uses the term to refer to patterns that foster the growth of constructive and creative impulses and behavior. Ethical values vary culturally, historically, and individually according to age and maturity, and also psychodynamically.

The author discusses how ethics enters into survival, as man's scientific and technological advances have multiplied at a dizzying pace. Complexities increase, and greater dangers to man are inherent. Advances in our understanding of man and "an ongoing development of an ethics in contemporary terms" accordingly become essential in order to keep pace and to thereby reduce the accompanying hazards to survival.

According to Levine, the most constructive type of thinking is dynamic, realistic, and integrative. It is necessary to the study and understanding of emotional conflicts and psychodynamics. Dependency is a significant source for early conflicts, as are hostile and sexual urges. Ethics involves the interplay, conflict, and relative harmony of the various forces that are inside the human animal. Indeed, the direct study of man reveals the primary importance of intrapsychic conflict. The author outlines and tabulates defenses, defensive ethics, and creative ethics.

Levine presents a beautiful discussion of the therapeutic alliance, carefully noting and illustrating many facets in its function, development, and operation. It is an experience in partnership. Its optimal operation contributes a basic and essential framework for the resolution of emotional conflict, the fostering of understanding, and the further development and maturation of individual ethical principles.

Contributions from psychiatry to the understanding and further development of ethical principles and behavior for both the individual and group are prominent in the major subareas of psychodynamics, personality development, psychopathology, psychotherapy, and psychoanalysis. In the study of man, especially from the ethical standpoint, a major emphasis is on the relationship and conflicts among the various forces inside him, with a secondary emphasis on his relationships and conflicts with the forces outside himself. The resolution of conflicts, in part at least, is the central issue of ethics.

I find it challenging and difficult to choose a few cogent samples from Maury Levine's fine and careful exposition that will do it justice for the prospective reader. But let me cite his call for three types of ego patterns that can be usefully so categorized and perhaps protectively elaborated in the further development of constructive or creative patterns of ethics. They are the stringent self-scrutiny of one's conscience, the stringent scrutiny of external standards, and the development of a strong ego pattern of cross-validation of internal standards by external standards, and vice versa. A comparable scrutiny by the group in turn is also essential.

I recommend this book without qualification. It is a fine contribution to the field and will be useful to psychiatrists and those in allied disciplines alike.

These are days of a rising tide of professional conscience and self-examination, accompanied by an approaching wave of government-sponsored peer review. At the initiation of this epoch this study is especially appropriate and timely.

Bethesda, Md.

Drug Use in America: Problems in Perspective. Second Report of the National Commission on Marihuana and Drug Abuse. *Washington, D.C., U.S. Government Printing Office, 1973, 481 pp., $2.60 (paper).*

Should one at first glance be inclined to pass over this volume and think it to be simply another drug report, that would prove to be a mistake, for the volume turns out to be a carefully considered, well-reasoned, authoritative examination of the drug

problem in America as seen in broad perspective. The commission reporting was a blue-ribbon group and had full authority and plentiful resources, and it used them both wisely and well. Composed of senators, educators, psychiatrists, and others, all of them outstanding, the commission read widely, heard numerous witnesses, and traveled through 36 nations in order to investigate firsthand the various facets of the drug problem.

After describing the phenomena of drug use, drug-induced behavior, and drug dependence, the report presents, among other things, a process for assessing the social impact of the problem. It notes that regardless of the country involved, there are common threads to be found that relate the concerns of various nations about the same subject. Our own nation, therefore, is not the only one currently exercised about the drug picture.

The first step toward resolving the drug problem, the panel states, should be a reconsideration of the present diagnosis of the ailment, for the present social response is a large part of the problem, and it is compounded by each unanticipated crisis. Preoccupation with the drugs must be replaced by an understanding of the behavioral impact of their use. The group then does its best to construct a coherent policy that, despite legitimate criticism, it believes should have a beneficial impact; and one can agree that it should. It warns that promises which cannot be kept must not be made. Disapproval of drug use is a part of a larger social pattern, and all the money and effort that American society can muster will never be able to deal effectively with this behavior if the problem continues to be defined as it is now. This statement should be sobering to the varied groups of experts who presently are ubiquitous and vocal and are holding forth, each sure that it has all the answers.

En route and as a small part of its examination, the commission notes the widespread use of alcohol and cigarettes in the general population. Although the vast majority of people do not regard either alcohol or tobacco as drugs, the panel notes that a significant relationship is found to exist between them and the use of drug substances. "While the use of alcohol and tobacco cannot be said to lead to other types of drug use, this behavior can be viewed as a precursor to, and a fairly accurate predictor of, other types of drug using behavior" (p. 45).

It would be unfair and injudicious for a reviewer to pick out various and sundry segments from the text of the report for comment, for the volume is packed with information on all aspects of the complicated picture, which now occupies the attention of the country at large. All angles of the situation are considered, and the panel seems to have missed nothing that might contribute to the solution of the present pressing national concern.

One frequently hears of the success of the so-called British system of heroin maintenance. In some quarters it is being strongly advocated, and suggestions are made that we follow it in the United States. The commission carefully examined that system and reports that "the individual and social benefits offered by Heroin Maintenance are insufficient under current conditions to outweigh its therapeutic disadvantages, and the risk of increased dependence." Adoption of the system at the present time, it believes, would be an irreversible act.

It is difficult to convey in a brief review the wide range of the investigation that this group undertook. Chapter 5 of its report, titled "Looking Ahead," is particularly important. It summarizes the objectives of the commission and sets forth its opinions about what might be done in the immediate future. It recognizes that policy makers must periodically rethink the basic issues and overhaul their responses. The panel believes that in four years the measures that they have recommended will have had time for a full trial. If they have failed, or even if they have only partially succeeded, a second complete evaluation will be necessary.

Thus, despite its thoroughness, the commission realizes that there are some questions not yet answered, and it frankly admits that only time and experience will show whether its recommendations are realistic.

In my opinion this is the best overall survey of the drug scene yet to appear. The book is particularly well written; it is free of jargon; and everyone who is interested in the drug problem as seen in broad perspective will be repaid amply by reading it.

F.J.B.

Alcohol and Health. Report from the Secretary of Health, Education, and Welfare. *New York, Charles Scribner's Sons, 1973, 360 pp., $3.95 (paper).*

This paperback report by a special task force chaired by Morris Chafetz, M.D., Director of the National Institute on Alcohol Abuse and Alcoholism, is to the Congress of the United States. It was mandated by the Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act of 1970, through Elliot Richardson, then Secretary of Health, Education, and Welfare. The report gives a broad but detailed account of this nation's most tragic, destructive, and costly public health problem. Alcohol abuse and alcoholism affect about nine million men and women in the United States, play a major role in half our highway fatalities, drain our economy of an estimated $15 billion a year, and account for 40 to 49 percent of all arrests.

This report brings together a substantial portion of the current scientific knowledge on the consequences to health of using, and especially of abusing, alcoholic beverages. The information is presented in language understandable to the layman as well as to the professional. A perspective of the history and epidemiology of alcohol use and abuse is given. In general, men drink three times as much as women, and alcoholic persons drink 11 times as much as others. Of 20 countries surveyed, the per-capita consumption of alcohol was highest in France, with Italy a close second and the United States seventh. Among American Indians the rate of alcoholism is as high as 25 to 50 percent. About one alcoholic out of six is a woman.

The effect of alcohol on the central nervous system as well as on other body organs and tissues is discussed. Alcohol-related illnesses are numerous and often severe. Causal theories of alcoholism include genetic, physiological, pharmacological, psychological, social, cultural, and deviant behavioral learning, all of which may contribute to a particular individual's addiction. This report presents the various and numerous modalities of treatment available but rightly stresses the need for individualization of treatment to fit the unique needs of the particular patient.

The legal status of alcoholism and intoxication in various states is discussed in detail and a plea made for treatment, rather than criminal punishment, while protecting at the same time the public safety. An appendix gives the particulars of the federally sponsored uniform Alcoholism and Intoxication Treatment Act as a guideline for state legislation.

Finally, this report outlines the need for applied research and the direction that it might take. The area of biomedical factors and cross-tolerances is mentioned along with more meaningful distinctions between alcoholic persons and individually suitable forms of treatment. The National Institute on Alcohol Abuse and Alcoholism will emphasize behavioral

science research toward better control, treatment, and prevention of alcoholism and alcohol-related problems.

FREDERICK LEMERE, M.D.
Seattle, Wash.

Evaluation and Management of the Violent Patient: Guidelines in the Hospital and Institution, *by John R. Lion, M.D. Springfield, Ill., Charles C Thomas, 1972, 74 pp., $6.*

More young psychiatrists should write books like this. Aimed at the beginning psychiatrist, it is neat yet inclusive and suitable for the older man and his continuing education. It tells what to say in a way that hearkens back to the real-life style of Carl Rogers' *Counseling and Psychotherapy* (1). In addition, it sets out the doctor's role with the violent patient, i.e., more medical doctor than psychiatrist and a teacher helping the patient to cope with inner helplessness and educating him to verbalize, to fantasize, and to recognize warning signs.

Violence is found in a large group of patients and is one of the problems that psychiatry can no longer avoid, especially with the courts and others demanding more public services. Thus it is timely to have this straightforward advice on how to comport oneself with the violent patient, how to manage feelings of staff and security officers, what to ask about weapons, and how to deal with (surviving) victims. Other matters, such as prediction of violence and making a show of force, are not indexed, but helpful hints are included all the same.

The book deals with adolescents as well as with older patients and should be useful in general hospital emergency rooms, outpatient settings, and most psychiatric inpatient services, including the alcoholism and adolescent wards of large hospitals. The chapter on treatment is particularly useful and should interest even those bound for the private office.

Most chapters conclude with choice, easily available references, including works by the author. The book ends with eight case examples and a resultant conclusion.

MORGAN MARTIN, M.D.
Norwich, Conn.

Mental Retardation: An Atlas of Diseases with Associated Physical Abnormalities, *by Lewis B. Holmes, M.D., Hugo W. Moser, M.D., Saevar Halldórsson, M.D., Cornelia Mack, M.S., Shyam S. Pant, M.D., and Benjamin Matzilevich, M.D. New York, Macmillan Co., 1972, 383 pp., $28.*

This is the most recent of the many books published over the past decade which have attempted to compile, for the benefit of the clinician, the many syndromes that involve chromosomal disorders, inborn errors of metabolism, neurologic disorders, and congenital malformations. As far as the field of mental retardation is concerned, this atlas is probably the most detailed and sophisticated that has yet appeared.

The authors begin appropriately with a discussion of mental retardation. However, at this point they should have inserted a bibliography of the basic texts and atlases that survey in great detail many of the disorders discussed in this work. The book itself is divided into seven chapters: "Metabolic and Endocrine Diseases," "Progressive Diseases of Unknown Cause," "Acquired Conditions Associated with Mental Retardation," "Chromosomal Abnormalities," "Central Nervous System Malformations," "Syndromes of Multiple Deformities," and "Neurocutaneous Syndromes with Mental Retardation." Each entity within these categories is fully discussed and accompanied by an excellent, up-to-date bibliography and at least six excellent photographs. The book is well indexed.

Although the classification system adopted by the authors is a good one, there should have been a much clearer organization within these categories. For instance, under the metabolic disorders, the various GM gangliosidoses could have all been assembled together, listing first GM 1 gangliosidosis and then the three variants of GM 2 gangliosidosis. Also, the discussion of the metabolic and endocrine disorders would have been facilitated by the use of chemical formulas demonstrating the metabolic pathways and the enzymatic defects.

The author's categorization of some entities is questionable. If the Prader-Willy syndrome is listed under endocrine disorders, why are the Riley-Day, Lowes, and Laurence-Moon-Biedl syndromes placed under syndromes of multiple deformities? Cretinism is appropriately placed under the metabolic and endocrine disorders, yet despite the authors' statement, most cases are athyrotic, thus representing a congenital maldevelopment. Some entities are included that are generally not associated with mental retardation, such as Riley-Day syndrome, ataxia telangiectasia, and thalidomide teratogenesis.

The so-called kinky hair syndrome, first described by Menkes in 1962, has now been found by Danks and associates (1) to be an inherited defect in copper absorption. Discussion of this syndrome should have been included in chapter 1, not in chapter 2. As the authors predict, there will be many more such changes in the future.

The poorest section is chapter 3, which deals with acquired conditions. Here prematurity and anoxia are omitted, yet erythroblastosis is included. Most irrelevant is a discussion of warfarin, where only two cases are known, and thalidomide, which is no longer available and did not cause mental retardation. Yet lead poisoning, mentioned in the introduction, is not separately discussed. This is a major omission. This whole chapter needs a careful revision.

In conclusion, one can say that this book is a valuable addition to the working library of anyone in the fields of mental retardation, genetics, neurology, and pediatrics. However, I feel that I should in all candor state that the publisher and authors alike should think twice before embarking on another such project. As the number of such books increases, the overlapping increases. It means one more book to buy and one more book to look up. It would be more profitable to revise those already available. I hope that the authors will be able to revise this book many times in the future.

Semantics: An Interdisciplinary Reader in Philosophy, Linguistics and Psychology, *edited by Danny D. Steinberg and Leon A. Jakobovits. Cambridge, Mass., Cambridge University Press, 1971, 599 pp., $16.50.*

This book is a splendid invention to meet the needs of the in-

quiring student in a wide-ranging area. It is what it purports to be, namely, an interdisciplinary reader or anthology of earlier outstanding articles by leading authors in three fields with major concern in semantics. It brings together 33 essays, most of which have been previously published elsewhere, by 34 authors, some of whom are well known not only in their own fields but also in the field of psychiatry.

Each of the three sections has a well-written overview. The overview for philosophy (pp. 3–13), by Charles E. Caton, gives us a good platform from which to plunge into difficult problems. Howard Maclay's overview for linguistics (pp. 157–184) is an excellent introduction to the complex tasks of defining the boundaries of an overexpanded linguistics and the future relations to psycholinguistics and human communications. The overview for psychology, by Danny Steinberg (pp. 485–495), gives us a quick view of the growth of behavior theory from the days when psychology had little to offer about an understanding of semantic problems to present-day efforts. This chapter alone will be helpful to those teachers who wish to discuss various facets of the problem of meaning with their classes.

The book is dedicated to Charles E. Osgood, a psychologist-psycholinguist at the University of Illinois who has worked on problems of aphasia and is a national leader in the area of psycholinguistics. Osgood has a chapter (pp. 497–528) on "Where Do Sentences Come From?" that will be of considerable interest to all clinicians and scientists interested in human behavior on several fronts. His searching inquiry into the roots of the presuppositions that lie behind the production of sentences leads him to survey wide horizons in linguistics, behavioristic psychology, and generative linguistics, with excellent critiques of their respective deficiencies to provide tenable models for "the speaker."

Osgood's presentation of a two-stage learning theory called "representational mediation theory," based upon his own contributions and the work of C.L. Hull (in the early 1930s and 1940s), Miller and Dollard (in the early 1940s), Mowrer, Goss, and the Kendlars (in the early 1960s), will revive many memories and hopes in readers who want a stronger and more stimulating learning theory on which to build experiments. Osgood closes with a few choice paragraphs on the problems of "language universals," with recommendations for further studies. This essay illustrates well the impossibility of doing justice to this book, because a genuine discussion of the articles would in most cases require space equal to the original.

I will try to mention most of the contributors by name in order to give the reader an introduction to them.

David McNeill, a linguist from the University of Chicago, has some sharp remarks (pp. 530–535) on "Are There Specifically Linguistic Universals?" Eric H. Lenneberg is represented by a chapter on "Language and Cognition" from his book *Biological Foundations of Language* (1). As might be expected, articles by Noam Chomsky, Jerry A. Fodor, George A. Miller, J.J. Katz, James D. McCawley, George Lakoff, Uriel Weinreich, D.T. Langendoen, and Paul and Carol Liparsky are reprinted. They cover their respective fields of competence such as the role of semantics in a grammar and the area of meaning, presupposition, and reference. The field of "the lexicon" is covered by articles by Charles J. Fillmore, Edward H. Bendix, Manfred Bierwisch, R.M.W. Dixon, and Kenneth Hale.

There are 12 essays representing "analytic philosophy," but I will not describe them or their authors because of space requirements and because they may be of less interest to clinicians than the articles previously mentioned. However, these 12 essays are well worth the hard work necessary to read them.

This book can be recommended with enthusiasm to all students of human behavior who want a genuine overview of the varied problems in semantics and language. It is a strong insurance against narrow provincialism. It will disappoint those who want easy answers to hard questions or cookbook formulas to approach the study of those subtle media by means of which we live together. We are just beginning to learn to define a very few primitive methods by which we can study human communication systems. We can hope for better insights into disordered behavior if we have better mastery of the communication process between living people.

HENRY W. BROSIN, M.D.
Tucson, Ariz.

Dementia Praecox and Paraphrenia *(facsimile edition), by Emil Kraepelin, translated by R. Mary Barclay. Huntington, N.Y., Robert E. Krieger Publishing Co., 1971, 328 pp., no price listed.*

This book is a translation of volume 3 of Kraepelin's eighth edition of his textbook of psychiatry (1). When it was published in 1919 it filled a need because English psychiatrists, not familiar with the German text, were not inclined toward Kraepelin's teaching. Now the book is valuable as a historical document, especially since numerous references offer an opportunity to become acquainted with the contributions of many little-remembered authors.

This book should be evaluated in the setting of Kraepelin's psychiatric development. In the fourth edition (1893), in which he formulated disease entities based on etiology and the course of the illness, he singled out manic-depressive insanity. In the fifth edition (1896) he presented his concept of dementia praecox, which included the largest group of patients in psychiatric hospitals. His publication offers a careful description of the manifold symptoms that he and others had observed. The illness was characterized by onset in adolescence and progress into a dementia of varying degrees. In the sixth edition (1899) he elaborated his unifying concepts, and he further did so in 1903. Although publications dealing with the onset of the illness in later life had appeared and were also confirmed by Kraepelin, he preferred to keep using the term dementia praecox.

In the period leading to the eighth edition (1913) the dynamic concept of psychopathology was stressed by the psychiatric group of Burghölzli (E. Bleuler, Jung), culminating in Bleuler's *Die Gruppe der Schizophrenien* (2). Kraepelin accepted Bleuler's separation of fundamental and accessory symptoms. He appreciated Bleuler's application of psychoanalytic interpretations but rejected Freud's theories. In the incomplete ninth edition (published posthumously by J. Lange in 1927) a more positive evaluation of Freud's work was offered. This edition did not include some clinical chapters (e.g., dementia praecox and manic-depressive disease). A publication by Kraepelin in 1920 (3) demonstrated his changing understanding of psychiatric classification. He stated that schizophrenic symptoms may occur in manic and depressive illnesses and manic and depressive episodes in a schizophrenic illness. Dementia praecox is considered a special entity in the group of schizophrenic illnesses.

It is of interest to note that Kraepelin doubted the importance of autism (introduced by Bleuler in 1911). In the period after Kraepelin and Bleuler, this feature became a central point

in treatment, especially through the influence of phenomenological psychopathology (L. Binswanger) and the clinical teaching of Manfred Bleuler. (His father had recognized the therapeutic importance of the correction of autistic withdrawal by early discharge from the hospital, and he later supported "prolonged sleep treatment" to permit a therapeutic contact.) Kraepelin's understanding of schizophrenic patients is illustrated by his inclusion of a patient's description of the early development of her acute schizophrenic illness. He also referred to Schreber's book (4), published in 1903 and analyzed by Freud in 1911.

The last part of the book includes Kraepelin's presentation of paraphrenia, a paranoid reaction that he separated from dementia praecox and related to Magnan's *délire chronique.*

The introduction to this facsimile edition, written by Ernst Harms, is an interesting discussion of the historical setting of 1913.

OSKAR DIETHELM, M.D.
New York, N.Y.

Organizational Diagnosis, *by Harry Levinson. Cambridge, Mass., Harvard University Press, 1972, 557 pp., $20.*

Sigmund Freud suggested two essential characteristics necessary for a reasonably successful life: "to love and to work." Psychiatrists have spent a great deal of time and energy discussing and writing about love. For reasons that are not totally clear, the psychiatric literature has paid little attention to the study of work.

Professor Harry Levinson has spent most of his professional life investigating and analyzing individuals in the world of work. His earlier books reflect his concerns regarding specific symptoms of individuals within corporations (accidents, absenteeism, and alcoholism). He stressed the point that the way in which organizations were managed had considerable impact upon the mental health of the people who worked in them. To understand emotional distress in industry, one therefore had to understand the organizational milieu as well as the individual at work.

His latest book, *Organizational Diagnosis*, is a "gathering guide"—a tool to be used by consultants as they attempt to analyze, synthesize, and establish dynamic formulations so that they may offer sophisticated recommendations to management.

Dr. Levinson uses psychoanalytic and systems theory to formulate his diagnostic model. He states:

> An organization is a living system. It has components, which taken together comprise its whole. These components interact with each other and comprise the whole with other wholes, and its own environment. It grows and develops, has a history, experiences crises, and adapts. An organization, then, is like any other living system. Therefore modes of systematically studying and evaluating other systems might be extrapolated to the study of organizations.

A significant part of the book is in outline form and addresses itself to three central questions: What data do you gather? How do you order it? What do you do with it?

Part 1 serves as a guide for using the outline and offers practical suggestions regarding entry into an organization. It also includes the various techniques involved in the study procedure, with specific emphasis on organizational structure, methods of sampling interviewees, and the observations of people at work.

The psychiatrist will feel very much at home with Part 2, for it parallels, to a certain degree, the classical psychiatric history. Levinson states, "The most highly systematized examinational procedure for a living system is that used for the physical and psychiatric examination of the individual person." This section contains the case study outline, which includes the genetic and historical data of a company, a descriptive analysis of the organization as a whole, interpretive data, dynamic formulations and conclusions regarding the company, and specific prognoses and treatment recommendations.

In Part 3 the principles of the organizational diagnostic process are used to analyze the Claypool Furniture Company.

Part 4 outlines the closure process, which includes preparing and presenting the report and anticipating the manager's reaction to it.

The psychiatrist should find Parts 1 and 4 to be the most interesting, primarily because they focus on the interpersonal dynamics between the consultant and the manager. These sections analyze some of the anxieties of both parties involved and the reactions (not always positive) to the recommendations of the consultant. Of particular interest is the predictable course that follows the reading of the report: the defensive hostile phase, followed by a discussion of feelings and issues, and subsequently leading to a stage of consolidation.

During the past 60 years an enormous amount of literature has been devoted to the field of organizational behavior. In the early 20th century Taylor and Gilbreth best exemplified the mechanistic, scientific approach regarding time and motion study in analyzing men at work. Then, in the late 1920s, 1930s, 1940s, and early 1950s, Mayo and Roethlisberger, of the Harvard Business School, pioneered the studies of human relations in organizational life. William White and Elliot Chapple, utilizing the principles of applied anthropology, and Kurt Lewin, utilizing the techniques of group dynamics, made further inroads in this area. Much of the literature of the 1950s, 1960s, and early 1970s owes its formulation to the works of Freud, Maslow, Rogers, and Merton, to name but a few.

This short history should give some indication of the overlapping of an incredible number of disciplines in the field of organizational behavior; hence the difficulty in trying to develop a diagnostic study outline.

This significant book could only have been written by a superbly trained "clinical academician," one who has organically enmeshed himself into organizational life and who has gathered together his unique experiences. It is clearly written and manifests great sensitivity to the client's feelings. As Professor Levinson states, "The consultant should be careful not to overwhelm the client with negative feelings, that leave him with disproportionate feelings of helplessness, therefore unable to act. He should make it clear that he is not there to tell them how to run their organization. His job is to gather organizational information."

This is not a cookbook; it is a guide, a tool to be used by individuals engaged in organizational consultation. No psychiatrist

can memorize this book and become an organizational diagnostic expert. It stresses the need for the consultant to be involved in the organization, and it further reinforces the need for a detailed history, perceptive clinical examination, and a sophisticated dynamic formulation before treatment and recommendations can be made. It follows the best tradition of medical practice. It is a most valuable book and, one may hope, will stimulate more psychiatrists to investigate individuals in the world of work.

BARRIE S. GREIFF, M.D.
Boston, Mass.

Symbol, Dream, and Psychosis, *by Robert Fliess, M.D. New York, International Universities Press, 1973, 425 pp., $13.50.*

This book represents the third and final volume of the author, a psychoanalyst who died in 1970. It begins with a chapter devoted to the symbol, then one that deals with various aspects of dreams, followed by one on ambulatory psychotic patients and one on what the author refers to as "exceptional states," primarily hypnotic in nature. There follows a section on technique, with a chapter on the analytic relationship, particularly as it relates to transference and countertransference. Then there is a chapter in which the author describes the technique of amnesia removal and finally one on the diagnosis and treatment of the ambulatory psychotic.

The author, the son of an internationally famous psychoanalyst, was obviously well acquainted with Freud's writings as well as with those of other prominent analysts. In most respects he agrees with Freud's basic proposals but in certain areas either expands or modifies them. For example, symbolism is a topic that does not lend itself to preciseness. To some patients certain symbols represent what we have come to consider traditional things, but in other patients such symbolism will vary because of their own backgrounds and even because of recent experiences. There are some patients who use dreams constructively, while others remain amnesic for their dreams and still others overwhelm the analyst with a plethora of dreams, to the point where it becomes impossible to deal with them all.

The author deals extensively with the problem of the sexually abused child. It is his contention that the majority of adult neurotics have been abused as children and that in most instances the adult abuser, usually a parent, was psychotic. Unfortunately, he does not make clear his differentiation between neurotic and psychotic but seems rather to assume that the reader will agree with this differentiation.

The book has many short case vignettes, but these are often so brief that they leave the reader wondering whether Dr. Fliess has drawn the correct conclusion.

Freud felt that many patients related childhood traumata that were in fact fantasy. The author feels that most of these are covered by amnesia of the true event and that, in fact, it or something akin to it did happen. He feels that such amnesia can be uncovered if properly handled.

In general, this could be described as a wordy book that often uses too many words to explain a concept and then does so in an unclear fashion. One could also take issue with the author's relatively casual use of the word "psychotic" as well as his frequent references to such parents as "beastial." Certainly one can agree that the use of symbolism, dreams, and the presence of psychosis may well be related in many patients. Unfortunately, in reading the book one gets the impression that the abused child almost invariably has a psychotic parent. More recent work on the physiology of sleep and the battered child is not included primarily because of the time at which the book was written.

This book might be somewhat helpful to the practicing analyst but will probably not find a wide market among general psychiatrists or the rest of the mental health professionals.

STUART M. FINCH, M.D.
Ann Arbor, Mich.

Genetic Diversity and Human Equality, *by Theodosius Dobzhansky. New York, Basic Books, 1973, 123 pp., $5.95.*

From time to time there appears a small book, deceptively easy to read, written usually by a distinguished thinker who has had a long and productive career, that illuminates an important area of human involvement and scientific thought. I have a special shelf for such books, and this one belongs on it. According to the dust jacket and the foreword, it purportedly deals with "the facts and fallacies in the explosive genetics and education controversy." Actually, this book by Dr. Dobzhansky, one of the world's foremost geneticists and an expert on evolutionary theory, contains three rich essays and is much more extensive in scope.

In the course of his discussion on genes and environments, the author indeed points out the importance of his concept of "reaction range"—"Similar genes may have different effects in dissimilar environments." In this context, while accepting the inference from family and twin studies that individual IQ differences have large genetic components, Dobzhansky remains unconvinced, on the basis of present evidence, that class and racial differences in IQ averages cannot be attributed to environmental factors.

Turning to broader issues, Dobzhansky roams over the topic suggested by the title of the book and in a fascinating manner develops the paradoxes posed by human genetic diversity. For example, if social and economic inequality is fixed by caste, class, or racial boundaries, the genetic potential of an individual has no chance to find its proper niche and reward. On the contrary, with freedom of opportunity to choose one's goals and be educated therefor, socioeconomic classes can give way to "aptitude aggregations," fluid from generation to generation, with genetics playing a larger, rather than a smaller, role in determining fitness and choice.

In an essay on the evolutionary genetics of race, the author forestalls any pejorative connotation by defining races as "subordinate Mendelian populations ... which differ in the incidence of some genes in their gene pools," with the classification of races a pragmatic affair rather then one based on eternal and mutually exclusive types. He discusses the roles of natural selection, random genetic drift, and gene exchange in the shifting evolution of racial groups, and he emphasizes the uniqueness of man, whose language and educability make possible cultural change as well.

It has sometimes been judged that the only ethics compatible with the concept of evolution is that of tooth and claw, of inequality and fierce competition. Dobzhansky does much in this book to point out that this may not be true, that man at least, cognizant of evolution, may work creatively with his fellows to obtain the maximum benefit for all and may discover value and perhaps even meaning in the process.

Psychiatrists as scientists, as humanists, and as citizens will

do well to put aside their more professional literature for an evening and read these essays.

JOHN D. RAINER, M.D.
New York, N.Y.

The Art of Dying, *by Robert E. Neale. New York, Harper & Row, 1973, 158 pp., $5.95.*

At first glance this book seems to be a manual for dying, a sort of do-it-yourself series of expositions or essays on death and dying, followed by questionnaires. The author refers to the latter as "exercises" for the reader to explore to discover his own feelings about the subject. But all this is deceptively simple; the book is actually a very profound one. It is "a descent . . . into the chaotic hell of our denial of death, fear of life and suicidal living."

Robert Neale writes in the existentialist tradition of Heidegger and Camus. His basic premise is that death is a highly personal experience, perhaps *the* most personal one, and in the flight from death one flees the self as well: "Our fear of death is our fear of life . . . a screen on which to project all our concerns about life." This connection between life and death is emphasized as the author draws from all aspects of life and literature to learn about death; then with grief as a hub he reverses to show that to deal with one's feelings about death is to confront one's existence, one's life.

The author is a parish minister, a chaplain, and currently Professor of Psychiatry and Religion at the Union Theological Seminary in New York. This experience, his philosophical bent, and the death of a brother have motivated him to search himself for his deepest feelings toward his own death and dying. This he shares with the reader, urging him to do the same without judgment as to what might be the right or wrong way to feel. This is so despite suggested answers to exercise questions that seem at times weighted in favor of a positive outlook, as if to lead the reader to awareness of a new point of view.

The author's style is easy and conversational, although at times somewhat sermonic. (Perhaps, because he is a clergyman, this is his idiom, and thus he is entitled to use it.) Since he draws on a wide variety of sources, the book is not a rigorously argued academic treatise, but rather an intensely personal essay offering one perspective on how to approach death. Because anxiety about death and separation, even in others, is a manifestation of our own introjected fears of oblivion, the death approached must be one's own. Oblivion may be not only a somatic death, but an existential death or flight from self as well. Thus approaching death (and therefore oneself) may enrich the quality of life; the art of dying is the art of living.

Neale feels that he is "trying to deny death in writing these exercises." We agree, but there is more. He is also trying to remove the mystery in and around his own death, thereby in a sense defeating, or at least mastering, death. Such an effort may be defensive, but it encourages utilizing defenses in coping with the inevitable rather than in a futile attempt at flight.

Yet the flight is not only the patient's. The goal of medicine is the promotion of life, not its prolongation; yet the physician often sees death (his own and others') as an enemy always to be resisted. In order to be truly helpful, the doctor must accept the ineluctable nature of death as a life event:

> We should not try to give the ego support by building up its hopes, prescribing medical remedies, or dispensing superficial consolations. We are to stop treating the individual as a patient who can be cured. We give up our own hope for the individual. By so doing, we become able to accept the individual's own experience. Then, in the keeping of a kind of death vigil together, the panic reaction diminishes, and with it the hasty assault on death (pp. 68–69).

Thus the efficacy of *The Art of Dying* is twofold: in its perspective on the helper-patient relationship and in the self-insight of the reader-therapist. (Incidentally, this quotation could well serve as a paradigm for insight therapy.)

The chapters are concerned with the degrees of awareness of death, the fears involved, suicide and all of its ramifications, grief and its tasks, "life in death" (concepts). These topics are subsumed under three sections: Death, Gestation, and Rebirth. While this book seems to be directed toward the clergyman, we feel that it makes a significant contribution to the problem of death and dying. It is appropriate for everyman. This includes the psychiatrist as well as those helping professionals more intimately involved with the dying. Robert Neale's book is a most welcome addition to the growing literature.

NATHAN SCHNAPER, M.D.
H. WILLIAM SCHNAPER
Baltimore, Md.

Group Therapy: 1973—An Overview, *edited by Lewis R. Wolberg and Emanuel K. Schwartz. New York, Intercontinental Medical Book Corp., 1973, 228 pp., $12.50.*

This is the first volume in an annual series that proposes to summarize the present status of group psychotherapy. "The emphasis is on the practical personal experience of recognized workers, and they explicate both traditional and advanced ideas," according to the publisher's flyer. There are 18 papers in this volume, authored by Alexander Wolf, Bernardo Neto, Hyman Spotnitz, Martin Grotjahn, Raymond Corsini, Irvin Kraft and Jody Vick, Bernard Riess, David Mendel, Asya Kadis and Max Markowitz, Harold Leopold, Helen Durkin and Henriette Glatzer, Leon Grinberg, Walter Schindler, Edrita Fried, Jay Fidler, Henry Ezriel, S. H. Foulkes, and E. James Anthony—certainly an impressive list of recognized workers.

I approach such annual volumes with an affective response similar to that aroused by a smorgasbord. I anticipate finding a few rare and delectable tidbits, disliking some rather intensely, and being indifferent toward the majority. Edited volumes are frequently uneven in the quality of their style and content. This small volume proved to be an exception. All the papers are well written, the introductory summaries are excellent abstracts, there is a wide sampling of issues, and the content is significant.

The subject matter ranges over acting out, treatment problems with adolescents, family therapy, transference-countertransference problems, training in group psychotherapy, variants of group techniques, group bonds, communication networks, and the dynamics of therapeutic effect. Two papers deserve special attention.

In "Psychotherapy of a Group of Deaf Mutes," Bernardo Neto describes his experience with five deaf mutes (three men and two women). "Fingers take the place of the mouth. Hearing is transferred to the eyes. . . ." Dr. Neto acquired the ability to use the deaf mute alphabet; he also demonstrates his ability to use the written word. He introduces the reader to the patients, then proceeds through the initial phases of this unusual group to the crisis that developed after six months of treatment, when he became more sure of himself. With candor, Dr.

Neto describes the countertransference issues that arose and his attempts to understand the growing chaos that developed around him and within him. That he was able to do so, and to let his patients know it, proved to be of immense help. I found this paper to be a sensitive narrative of a therapist's real struggle to help a group of uniquely disadvantaged people as well as an allegory of "every therapist's" struggle with the therapeutic situation, his patients, and himself.

Many attempts have been made to discuss transference, transference neurosis, the technique of transference interpretation, and transference in groups. In "Psychoanalytic Group Therapy" Henry Ezriel offers one of the most succinct discussions of these issues that I have encountered. I recommend this paper to all students of psychotherapy and psychoanalysis as well as to those specifically interested in group psychotherapy.

This first volume is presented by the editors as a memorial to Asya Kadis, the former director of group therapy at the Postgraduate Center for Mental Health. It is a fitting tribute to her. Subsequent to the publication of this volume Emanuel K. Schwartz, one of the editors, suddenly and tragically died. This volume thus becomes a memorial to him as well. It is hoped that future editors will maintain the high standards that Drs. Wolberg and Schwartz established in this first volume.

STANLEY L. BLOCK. M.D.
Cincinnati, Ohio

Human Sexuality and the Mentally Retarded, *edited by Felix F. de la Cruz and Gerald D. LaVeck. New York, Brunner/Mazel, 1973, 340 pp., $8.95.*

There are precious few issues in the care and management of the mentally retarded which precipitate the amount of direct verbalizations and feelings that the topic of their sexual adjustment does. Unfortunately, these frequent and swirling discussions often generate more heat than light on the crucial issues involved in this area of human adjustment.

Although the sexual dimension of the symptom of mental retardation has been a traditional focus of study for psychiatrists involved in this area of clinical endeavor, there have been many recent events that have drastically altered the "traditional" issues involved. For example, the recently published longitudinal studies of the sexual adjustment of large groups of young retarded citizens, the Pill, the rapid move toward community-based programs for the retarded (coupled with citizen advocacy programs)—as well as other recent trends—strongly suggest the need for a current review of this area.

The editors of this book set out to capture the current professional ferment in this area by initially having an international conference (in late 1971), then editing the conference proceedings and publishing them in this book. In the preface they state that they wanted to review what is known and what remains to be studied about the role of sexuality in the development and behavior of the mentally retarded. They sought a balance between the biological-developmental approaches to this particular facet of the symptom of mental retardation and the subjective-personal needs and societal expectations of retarded citizens within the mainstreams of our society.

The book includes 22 contributions, which are arranged into four sections: psychosocial development and sex education, physical and biological aspects, institutional and community attitudes and practices, and new clinical directions for research and experimental programs. The first section contains four excellent presentations on the developmental aspects of sexuality in the retarded, including the issues involved in providing sex education within the learning environments of retarded citizens.

The second section focuses on family planning programs, methods of contraception, and the possible epidemiological impacts on the gene pool of the currently changing pattern(s) of sexual expression among the retarded. Each of the four contributions in this section presents a fine balance between succinct theoretical foundations and pragmatic guidelines.

The third section of this book, titled "Institutional and Community Attitudes, Practices, and Policies," is a remarkable collage of national-international studies on the patterns of sexual expression of the retarded in a variety of residential settings, the impact of community attitudes on expectations, and moral-ethical-legal dimensions of sexual relationships among the retarded. These presentations reflect the actual experiences of clinicians in a variety of settings, and the theoretical aspects are interpreted within their respective frameworks of service and experiences. Each of the seven contributions to this section is a gem.

The next section deals with research and includes an endocrinological focus on the development of systems and mechanisms for expressing sexuality in adults, as well as social-cultural research considerations. Included is a very lucid review of possible future research studies that would integrate cultural and biological factors into specific research strategies for directly altering the expression of sexuality in the adult retardate. The concluding section of this book, "Background Papers," provides an international perspective on sex education replete with analyses of recent survey data on the rapidly changing trends and attitudes toward premarital and postmarital sexual behavior.

Each of the five sections of this book includes a synopsis of the question-and-answer exchanges that followed the initial presentation of these papers. These discussions are a distinct highlight of the book, since the discussants are nationally known individuals in the field of mental retardation and they focus directly on both current issues and those challenges which are on the professional horizon at this time.

The editors have accomplished a prodigious effort in presenting a publication that is of uniformly high quality as to the contributions included, well-balanced as to national-international trends, and in an interesting, readable format. The contributors to this book, by their in-depth approach to the special issues inherent in their topics, have provided an interesting and most timely assessment of the general and specific dimensions of the expression of sexuality by "deviant" (or "normal"!) citizens in our society.

FRANK J. MENOLASCINO, M.D.
Omaha, Neb.

The Analysis of the Self: A Systematic Approach to the Psychoanalytic Treatment of Narcissistic Personality Disorders *(Monograph Series of The Psychoanalytic Study of the Child, no. 4), by Heinz Kohut, M.D. New York, International Universities Press, 1971, 343 pp., $12.50.*

This book is a finely done intaglio. The central focus is on those unfortunates who never successfully master the critical step from childhood narcissism to the broader world of reasonable balance between narcissism and object relations. Kohut manages in just over 300 pages to sketch and then to etch in the reader's memory this imbalance, which he calls narcissistic per-

sonality disorder. The text shifts from clinical to theoretical with great effectiveness. The intaglio effect is achieved by reading the entire manuscript in which all these things are shown in precise relationship to the narcissistic imbalance: genetic development in the psychoanalytic sense, the relationship of narcissistic disorders to other clinical entities, the treatment problems that are unique for this formerly untouchable area of human psychopathology, the special problems of countertransference that such patients arouse in most persons who meet them as well as in those who treat them, and some special gains by squarely and fairly meeting the varieties of transference demands made upon the analyst—for example, greater creativity, empathy, and, at times, humor.

The information given in this book was hard won and represents years of both clinical and theoretical experience. For the therapist to make use of this information will require more than hard work. In the first place, it will interest only those therapists who are willing to expose themselves for long periods of time to the vicissitudes of the human psyche. Those looking for short cuts or answers will not like Kohut's manner or message. In the second place, since this monograph represents what may well be the signal work in a new area of psychoanalysis, it can be read profitably only by those who have some familiarity with psychoanalytic literature. Certainly the reader need not be a fully trained psychoanalyst, but he should not have to struggle with the fundamental assumptions of analysis, at least in their evolving theoretical aspects. In the third place, the reader should identify his own capacity for two things before attempting this book: his ability to retain ideas over long Germanic sentences and over the entire scope of the book and his own exposure to clinical material from his own experience to enliven the text and make its reading a true learning experience.

If these several conditions can be met, the book will more than repay reading and rereading. It should prove especially helpful to the thoughtful practitioner who has to depend upon his own reading and his own practice to grow in therapeutic skill. Psychoanalysts will find some points to argue with, but will also find the book on the must reading list for some time to come.

RAYMOND HEADLEE, M.D.
Elm Grove, Wis.

Fact and Fantasy in Freudian Theory, *by Paul Kline. New York, Barnes & Noble (U.S. distributor), 1972, 394 pp., $16.*

In this book Dr. Kline reviews a large number of studies that have subjected various parts of psychoanalytic theory to empirical tests. He has undertaken this task because he believes that while the validity of all of psychoanalytic theory has not been established, there is no theory that better explains the many observations on which it is based and there is no evidence that refutes the entire complex.

His aim is to establish which parts of Freudian theory have been or could be confirmed by objective scientific research. His criteria for objective research are that the sample and controls be adequate, that the tests used to establish validity be valid themselves, that the results be capable of statistical analysis, and that the conclusions of the study be relevant to psychoanalysis. He acknowledges that he cannot review all of the hypotheses contained in Freud's writing, but has chosen those which he considers to be most significant. Dr. Kline reports the experiments in reasonable detail. He critically reviews the validity and reliability of the conclusions and discriminates between those studies which he believes validate analytic theory, those which refute it, and those from which no conclusions can be drawn.

Dr. Kline's book presents two major problems. One is the issue of validation of theory in disciplines such as psychoanalysis where the data do not easily lend themselves to mensuration. Only in the physical sciences can the variables be adequately isolated and held sufficiently constant to easily demonstrate cause and effect. In the biological and social sciences such an approach is often extremely difficult because the phenomena studied are in a state of flux and because they are multidetermined. Variables cannot be easily isolated or manipulated. Knowledge in these areas is acquired largely through a historical approach, i.e., observation over a period of time. The genetic approach is basic to psychoanalysis, and any consideration of its validity has to take this into account.

The studies reported by Dr. Kline deal, for the most part, with contemporary attitudes. Even when they include historical data, these are arrived at by the recall of material readily available to consciousness. This disregards the possible importance of factors of which the subject may not be aware and of which he can become aware only over a period of time. The problem of measurement is further complicated by the validity of the measuring tools. In the studies reported the tools used, such as questionnaires, rating scales, and inventories, are not of the same order of precision as the tools used in the physical sciences, and therefore the results are less definitive and are difficult to evaluate.

The second problem encountered in this book is that of definition and interpretation of psychoanalytic concepts. That Dr. Kline is aware of the complexity of the subject is indicated, for example, by his discussions of both the changing concept of defense and the difference between imitation and identification. However, he sometimes tends to accept simplistic, outmoded, or even inaccurate concepts. This is illustrated in parts of his discussion of dreams, homosexuality, and the structural theory.

Attempts to correlate the knowledge gained from statistical analyses and direct observations of behavior with the insights gained from psychoanalysis are particularly pertinent at this time when learning theorists, behavior therapists, and psychoanalysts sometimes fail to recognize the areas in which their interests overlap and present their ideas as if they were mutually exclusive. While pointing out some of the difficulties encountered in attempting to demonstrate these correlations, Dr. Kline also indicates some areas in which they occur. While there is reason to question some of Dr. Kline's assumptions and judgments, his book presents an extensive and well-organized review of the subject and could be helpful to those working in this field.

REBECCA Z. SOLOMON, M.D.
Hartford, Conn.

Homosexuals and the Military, *by Colin J. Williams and Martin S. Weinberg. New York, Harper & Row, 1971, 214 pp., $8.95.*

This sociological research study involved an experimental design in which a comparison was made between a group of men who received honorable discharges from the armed services and a comparable group who received less than honorable discharges, all having been identified as homosexual.

Background statistics indicate that at least 90 percent of service personnel leave with honorable discharges, five to six percent with general or undesirable discharges, and one percent or

less with bad conduct or dishonorable discharges. Educated guesses suggest that perhaps 2,000 separations per year were for homosexual reasons during the late 1940s to mid 1950s. Available statistics do not provide accurate information as to the type of discharge given.

The research sample was selected from completed questionnaires sent to homosexuals in New York City and San Francisco. Of 872 questionnaires sent to members of the Mattachine Society of New York, there were 51 returns by individuals who gave permission for an interview and who had had military experience. Of 500 questionnaires sent to members of the Society for Individual Rights in San Francisco, there were 85 "useful" returns. In all, there were 32 individuals who had received less than honorable discharge due to homosexuality. A similar, matched control group was randomly chosen from the remainder, i.e., those who had received honorable discharges and whose homosexuality had not been discovered. Two central questions guided the research: How does a person become officially labeled as homosexual, and what are the consequences of leaving the military with less than an honorable discharge?

In answer to the first question, there seemed to be three main patterns: those who were caught through their own indiscretion, those who voluntarily admitted homosexuality in order to leave the military service, and those who were discovered through another person. The third pattern was the most common, although the authors give no figures. There were no "bum raps" reported. In answer to the second question, the authors conclude that while the less than honorable discharge may initially be very traumatic, most persons do not suffer any long-term negative effects.

The authors found no significant differences in the effects of an honorable versus less than honorable discharge on the subsequent lives of homosexuals. Nonetheless, in an epilogue they give their personal opinion that military policy concerning homosexuals is unwise, unjust, unenforceable, and immoral. While the authors may be right, their opinions are not supported by their research.

JOHN M. CALDWELL, M.D.
Miami, Fla.

Development of an Urban Mental Health Center, *edited by H.G. Whittington, M.D. Springfield, Ill., Charles C Thomas, 1971, 199 pp., $9.50.*

Dr. Whittington and eight co-workers recount here their experience since 1965 in establishing a comprehensive mental health program to serve over half a million people in the city and county of Denver, Colo. Most of the book deals with the specific programs established for 200,000 people in northwest Denver, a large number of whom are Spanish-American and black and a major proportion poor.

The first several chapters, written by Dr. Whittington, succinctly state the philosophy, basic principles, and administrative procedures upon which program planning is based. Phrases such as "clinical problem solving" and "pragmatic utopianism" are translated into action programs. The involvement of community institutions and agencies and the focus on a family approach to individual problems are constant themes interwoven in all discussions of programs. Dr. Whittington also states his functional criteria for defining a comprehensive community mental health center—"a new 'service delivery system' designed to correct deficiencies in the multiple systems which preceded it" (p. 26). The criteria begin with the question "Does the agency reflect in its beliefs and programs, the conviction that human behavior and misbehavior are in part socially rooted?" It also includes an emphasis on preventive aspects of psychiatric practice, flexible use of therapeutic and preventive modalities, and redeployment of professional resources. It ends with the question "Do citizens participate in policy setting?" (p. 28).

The Denver program is subdivided into geographic catchment areas with a multidisciplinary team assigned to each subarea. Two teams are stationed in neighborhood health centers. Each team is responsible for all adult and child outpatient, consultation, and follow-up services. Inpatient and day-care services are centralized in the Denver General Hospital, with each team assuming regular care and contact with patients from its designated catchment area. This method of functioning appears practical and economical. For instance, each generic team spends about 50 percent of its time in direct clinical services (15 percent in evaluation, 15 percent in individual treatment, and 20 percent in group therapy), 15 percent in treatment and preventive activities for alcoholics, ten to 25 percent in consultation, and 15 percent in record keeping, team communication, and administration.

The contributors describe their individual experiences: the nurse in the emergency room, the rehabilitation counselor assigned to a team, the development of a generic team stationed in a neighborhood health center, and the planning of a comprehensive and accessible program in another neighborhood health center. They also describe how the hospital program meshes with the generic teams and the development of a program for long-term institutionalized state hospital residents now living in community boarding houses or other types of homes. The chapter on child services is noteworthy because the Denver program has made sustained efforts in this high priority area to which only lip service is so often given. There is also a chapter on alcoholism, which describes the numerous problems inherent in building an adequate program.

A final chapter on area-wide planning points out that population mobility and the dispersed dwellings of most people do not fit with the concept of a geographic catchment area. However, Dr. Whittington does not suggest alternative approaches. Nor does he discuss citizen participation, to my disappointment.

The book is well written and makes its points with brevity. It fills a gap in a field relatively devoid of teaching texts and will be of interest to both professional and lay people. The book is a descriptive story in most part. Program evaluation is forthcoming, the editor says, but has not yet been achieved. However, he is encouraged by the Denver experience and is hopeful that community psychiatry is moving toward achieving its goals.

LUCY D. OZARIN, M.D.
Rockville, Md.

I'm OK—You're OK: A Practical Guide to Transactional Analysis, *by Thomas A. Harris, M.D. New York, Harper & Row, 1969, 267 pp., $5.95.*

I recall the consternation and the professional "explanations" when the smashingly successful Beatles arrived on the scene: "They appeal, through long hair and shaking, to bisexual tendencies"; "They offer 'release' from repression." Overlooked by many was that they were good, very good, extraordinarily good.

The same was true for tough Tony Galento, heavyweight prize fighter of East Orange, N.J. His form left a lot to be desired. He just kept coming in, punching, punching, punching—never stopping. Also good, very good.

I'm OK—You're OK, by Thomas A. Harris, M.D., has been in print since 1967. By now almost one million copies have been sold. Why so much interest? Why is this book "alive" six years later? Why is *I'm OK—You're OK* so widely read?

After a takeoff as long delayed—but in no way as gripping—as an overloaded 747 departing from a muddy runway on a hot day, the theme unfolds: In every person exists *P*arent-*A*dult-*C*hild, P-A-C for short. *P*arent is a combination of punishing superego, Jewish mother, "Uncle Sam wants you!" and a call from the bank about insufficient funds. *A*dult is old Jean Hirsholt as Dr. Christian, radio's Ma Perkins, and Senator William Fulbright. *C*hild, well, you have the idea. Also, the various possible combinations of "you and me," OK and Not-OK are reviewed—and the right answer is I'm OK—You're OK.

Dr. Harris makes it clear that the stakes are high, really high!

> Society cannot change until persons change. We base our hope for the future on the fact that we have seen persons change. How they have done it is the good news of this book. We trust it may be a volume of hope and an important page of the manual for the survival of mankind.

The basic words of Transactional Analysis (Parent, Adult, Child, NOT OK, OK, games, and stroking) are so simple that even if it were not possible to translate them into all other languages, they could be used as they are, with definitions in the words of those languages. "OK" is already an international word. *P*arent, *A*dult, and *C*hild could also become international words.

Yet, the sense of revealed truth aside, the book is sincere, dedicated, sometimes very wise, sometimes deeply touching. A section titled "Teaching P-A-C to the Retarded" is a particularly moving example of "P-A-C— I'm OK—You're OK" as a tool and philosophy for helping, rather than describing or explaining, human suffering.

En route, author-therapist Harris is revealed as a sincere, dedicated, humane clinician. His commitment to teaching P-A-C is personally intense for him—and undoubtedly inspiring for his patients.

Simple? Perhaps. Contrived? A bit. Naïve? Who knows? Still, Dr. Harris' and Dr. Berne's ideas have a unity to them. People can understand them. In Dr. Harris' hands they have a certain persuasiveness. Further, each person can "try it on for size" and use it if it works for him.

I enjoyed the book. I got something from it. I suspect that the 500,000 people who each told somebody else, "I'm OK—You're OK—it's OK—buy it" felt the same way.

OFFICIAL ACTIONS

Report of the Secretary: Summary of Meetings of Board of Trustees and Executive Committee May 1972–May 1973

IT IS MY PRIVILEGE to report for your information and approval the actions of the Board of Trustees since the last annual meeting. At the conclusion of this report I shall request your ratification of the actions. The Board of Trustees has approved these actions now presented to you, the members.

Most Board actions result from specific recommendations from the committees—recommendations that may originate in a specific committee or result from study and investigation of a problem referred to a particular committee. Recommendations for action also come to the Board from the Assembly of District Branches.

Referrals to committees or individuals are not included in this report since they are being investigated or studied for recommendation to the Board at a later date. Also omitted are the various presidential appointments reported to the Executive Committee and to the Board throughout the year.

I would like to call to your attention the fact that in order to keep the membership informed of developments and new policies, it has for several years been the custom to circulate minutes of each Board of Trustees and Executive Committee meeting to the president, secretary, and delegate of each district branch. In addition, the branches are invited to send representatives to each meeting of the Board; these representatives are always welcome.

For my report, I have divided the actions into several categories, beginning with fiscal matters. In these actions the Board (or the Executive Committee acting as its agent):

FISCAL MATTERS

1. Reaffirmed authorization for an expenditure of up to $200,000 for purchase of a site for expansion of APA headquarters, and noted further the availability of $1,000,000 for the construction and furnishing of the additional space required (Ex.C., June '72).

2. Noted the intention to accumulate a surplus of funds sufficient to defray the operating expenses of APA for one year (Ex.C., June '72).

3. Authorized the Medical Director to employ whatever legal services are necessary to fight the unrelated income tax ruling of the Internal Revenue Service (Ex.C., June '72).

4. Authorized setting aside $1,000 from funds remaining in the pooled councils' balance to print 3,000 copies of a *1972 National Directory of Providers of Psychiatric Services to Religious Institutions* if the Council on Professions and Associations cannot absorb all the cost (Ex.C., Sept. '72).

5. Authorized expenditure of up to $10,000 to hold an additional special ad hoc meeting of the Board of Trustees for policy discussions (Ex.C., Sept. '72).

6. Approved restoring $5,000 to the 1973 annual meeting budget to provide for shuttle bus service in Hawaii (Bd., Dec. '72).

7. Approved and accepted the entire budget for fiscal year 1973–1974, including the one change noted regarding increase in the membership fees for the Council of Medical Specialty Societies (Bd., Dec. '72).

8. Approved increasing the travel budget for area council meetings of the Assembly of District Branches from $5,000 a year to $8,500 a year (Bd., Dec. '72).

9. Approved increasing the budget of the AMA Section Council on Psychiatry from $350 to $3,500—to reflect the wish of the Board of Trustees in its April 1972 meeting that an interim meeting of the Section Council be authorized for a two-year trial (Bd., Dec. '72).

10. Approved expenditure of $12,558 from the accumulated proceeds of the Second Psychiatric Knowledge Self-Assessment Program (PKSAP-II) to fully fund salaries and pay additional office expenses of the Office of Continuing Education for Psychiatrists for its operation during the year (Ex.C., Sept. '72).

11. Approved use of funds as they accumulate (over and above the $12,558) from receipts of the PKSAP-II, up to the amount of $59,000, for the research phase of the project, but recommended to the director of the Office of Continuing Education for Psychiatrists that he try to find other sources of funding—either private foundations or different approaches to government funding (Ex.C., Sept. '72).

12. Declined a request to authorize the expenditure of up to $7,000 in connection with expanded operations of the Government Relations Section and encouraged the district branches to hold their own area meetings of legislative representatives (Ex.C., Sept. '72).

13. Authorized a loan of $151,815 as requested by the American Psychiatric Museum Association, Inc., in December 1971 for its fiscal year, Oct. 1, 1972, to Sept. 30, 1973. (Noted approval of budget estimate of Museum expenses for 1973–1974 in the amount of $166,723.) (Bd., Dec. '72)

14. Approved adding $5,000 to the Museum budget for part-

This is an edited version of the report presented by the Secretary at the annual business meeting in Honolulu, Hawaii, May 8, 1973.

time and temporary help (Bd., Dec. '72).

15. Authorized an expenditure of up to $30,000 for supplementary expenses of the Manpower Research and Development Division, to cover items as presented by the Treasurer: 1) to complete coding and analysis of responses to the 1970 APA census of psychiatrists; 2) to pay a systems design analyst to advise on the operation of the system and its redesign; and 3) supplementary costs for securing data not obtained in the February survey. This data will also make possible a directory of residency training centers (Bd., Dec. '72).

16. Reaffirmed a mail vote of the Executive Committee in favor of drawing up a contract to fund the revised computer program of the Manpower Research and Development Division and its national retrieval system (Ex.C., Feb. '73).

17. Denied a request for a $7,000 appropriation to the Physician Education Project, for additional staff (Ex.C., Feb. '73).

18. Authorized withdrawing $36,000 from investments for deposit in the miscellaneous financial expense account, in order that APA employees may receive a five percent salary increase on April 1, 1973 (Ex.C., Feb. '73).

19. Authorized an extra $500 from the Board of Trustees Contingency Fund to cover APA's increased share of costs, from $2,500 to $3,000 per year, for the Joint Commission on Accreditation of Hospitals (JCAH) Accreditation Council for the Facilities for the Mentally Retarded (Ex.C., Sept. '72).

20. Authorized payment of $1,932 in dues, for APA's share of costs for one year, to the Council of Medical Specialty Societies, for input into the medical policy body—money to come from the Board of Trustees Contingency Fund (Ex.C., Sept. '72).

21. Disapproved a request to lend $20,000 to an unnamed refugee colleague as being against APA policy (Ex.C., Sept. '72).

22. Approved APA's acting as fiscal and administrative agent for the American Association of Psychiatric Services to Children through January 1, 1973, at a monthly service charge of $100, and noted receipt of a $6,000 check for initial expenses (Ex.C., Sept. '72).

23. Authorized funds to cover the increase in cost for a seat on the JCAH Accreditation Council for Psychiatric Facilities from $2,716 a seat to $3,000 a seat—or an increase of $852 for APA's three seats on the Council (Bd., Dec. '72).

24. Authorized expenditure of up to $500 for a breakfast meeting with members of Congress and their staff members, the funds to come from the short-term investment account (Ex.C., Feb. '73).

25. Denied a request from the student AMA representative for travel subsidy to the APA annual meeting in Hawaii (Ex.C., Feb. '73).

26. Denied a request for funds from the National Conference on Citizenship (Ex.C., Feb. '73).

27. Authorized a $1,000 contribution to the Coalition for Health Funding, to assist with salary, postage, materials, duplicating, and other expenses of maintaining its office (Ex.C., Feb. '73).

28. Took no action to grant a contribution for support of a research project by the Foundation of the American Society of Association Executives, Inc., or for two other specific requests for contributions—from the National Council on Aging and the National Council on Alcoholism (Ex.C., Feb. '73).

29. Requested the Budget Committee to review the whole policy of contributions to other organizations and to come up with a standard rule (Ex.C., Feb. '73).

30. Authorized the Medical Director to file a grant proposal on the development of action-oriented recommendations that would lead to a more favorable distribution of psychiatrists in relation to the needs of four populations: rural, poverty, minority, and the seriously mentally ill (Ex.C., June '72).

31. Authorized the American Psychiatric Museum Association, Inc., to file a grant application for $60,000 on behalf of the APA Commission on History, to develop a project on the Oral History of United States Psychiatric Achievement, 1938–1970 (Ex.C., June '72).

32. Authorized the Task Force on Indian Affairs to negotiate a one-year contract of $25,000 with the Indian Health Service for a study of mental health problems among Indians (Ex.C., June '72).

33. Authorized the Council on International Affairs to seek funds from outside sources in support of the Second Inter-American Congress on Mental Health of Children and Youth, to be held in Puerto Rico, Sept. 28–Oct. 3, 1973 (Bd., Dec. '72).

34. Authorized the Task Force on Psychiatric Involvement in Family Planning to seek outside funding to plan and conduct a conference on the psychosocial and psychocultural aspects of family planning (Bd., Dec. '72).

35. Authorized the Task Force on Family Life Education to seek outside funding for a national conference to promote mutual understanding of the roles of psychiatrists and other professionals in family life education (Bd., Dec. '72).

36. Authorized the Medical Director to seek a grant from NIMH jointly with Mr. James Mitchell of the Advanced Study Section of the Brookings Institution to support another public policy conference jointly sponsored by APA and the Brookings Institution (Ex.C., Feb. '73).

37. Approved APA's endorsement of an application for a grant by the department of psychiatry at Harvard University to the National Library of Medicine to produce films on emergency psychiatric services, with the understanding that the APA seal of sponsorship not appear on the film unless the final product has been reviewed and approved (Ex.C., Feb. '73).

MEMBERSHIP MATTERS

1. Reaffirmed the intent of the Constitution and By-Laws that a member dropped by either APA or a district branch may not be a member of the other group (Ex.C., Sept. '72).

2. Dropped from APA membership 57 members who were three years in arrears in dues as of March 31, 1972, who had been extended until September, and who had not responded to repeated efforts to collect (Ex.C., Sept. '72).

3. Took individual actions in the cases of 13 other members who had been listed as three years in arrears in dues as of March 31, 1972 (Ex.C., Sept. '72).

4. Endorsed the Assembly's approval of the recommendation of the Commission on Future Planning that there be no new class of membership in APA at this time (Bd., Dec. '72).

5. Endorsed the Assembly recommendation for family membership in APA, with dues at the rate of 150 percent of individual membership, and referred the matter to the Membership Committee for consideration (Bd., Dec. '72).

6. Rescinded the action taken by the Executive Committee in September 1972 of dropping nine members who had since paid dues that were previously three years in arrears (Bd., Dec. '72).

7. Individual actions on the membership status of others were taken or postponed, as recommended by the Membership Committee (Bd., Dec. '72).

8. Accepted the recommendation of the Committee on Membership and, waiving the requirement of a five-year general membership, elevated Dr. H. Keith H. Brodie to the status of Fellow in APA, as of May 1973 (Ex.C., Feb. '73).

9. Rescinded a previous dropping action in a case where all back dues have now been paid, in accordance with the recommendation of the Membership Committee (Ex.C., Feb. '73).

BALLOTING

1. Approved individual suggestions made by Executive Committee members for changes in the body of the report of the Ad Hoc Committee on Election Procedures (Ex.C., Sept. '72).

2. Accepted the report of the Ad Hoc Committee on Election Procedures and dissolved the committee (Ex.C., Sept. '72).

3. Considered the Ad Hoc Committee on Election Procedures' suggested addition to the section on balloting regarding plurality of votes when three or more candidates run for one office (Ex.C., Sept. '72, and Bd., Dec. '72).

4. Referred the question of election by majority to the Assembly, with a definite charge to contact the district branches with the specific question, "Do you approve election by plurality or majority?" (Ex.C., Feb. '73)

5. Approved the proposal of the Ad Hoc Committee on Election Procedures, as recommended by the Assembly's Executive Committee, that in the event district branches who choose to campaign within their jurisdictional areas require financial support for such campaigning, such financial support be supplied by solicitation of voluntary funding, and that in no case dues be utilized for campaigning purposes (Ex.C., Feb. '73).

CONFERENCES

Approved holding a second Institute on Government Operations in March 1973, approved accepting of a $5,000 grant from Smith Kline & French to fund faculty and administrative costs, and approved setting aside $3,600 in APA funds from the valuation reserve account for the Institute ($2,000 for implementation of the meeting itself and $1,600 for a meeting of the steering-planning committee), to supplement the funds of Smith Kline & French (Ex.C., Sept. '72).

PUBLICATIONS

1. Approved publication of a summary of APA position statements from 1948 to 1972, *Official Position Statements of APA in Précis Form* (Ex.C., Sept. '72).

2. Authorized staff to seek methods of underwriting the cost of wider distribution of *Prospects and Proposals: Lifetime Learning for Psychiatrists* (Bd., Dec. '72).

3. Approved publication of a *Position Statement on Peer Review in Psychiatry*, the document submitted by the Task Force on Peer Review and cleared by the Assembly (Bd., Dec. '72).

4. Asked the Division of Public Affairs to publish, with the help of an advisory committee, a pamphlet on the rights of the mentally ill and mentally retarded consumer (Bd., Feb. '73).

5. Approved, as amended, the proposed recruiting pamphlet for residents in training, which will be issued under the title *We're Involved! Are You?* (Ex.C., Feb. '73)

6. Asked the President to appoint a subcommittee of the Board of Trustees to review the document being prepared on alternate methods of funding residency training, in addition to final review and approval by the Advisory Committee—Project to Develop Alternatives to Funding of Psychiatric Residency Training (Ex.C., Feb. '73).

POSITION STATEMENTS AND RESOLUTIONS

1. Accepted the Report of the Task Force on the Status of State Psychiatric Hospitals for printing in an Association publication (Ex.C., June '72).

2. Approved the Assembly resolution recognizing the psychiatrist's office as a legitimate psychiatric facility (Ex.C., June '72).

3. Approved in principle the Assembly resolution providing that all position statements be reviewed by the Assembly before presentation as official policy of APA, contingent upon the Executive Committee of the Assembly's developing a satisfactory mechanism for implementation (Ex.C., June '72).

4. Approved the Assembly's position statement, "National Health Insurance—A Statement of Principles" (Ex.C., Sept. '72).

5. Approved the position statement developed by the Task Force on Interprofessional Relations ("Position Statement on Psychiatrists' Relationships with Nonmedical Mental Health Professionals"), which had been cleared by the Assembly (Bd., Dec. '72).

6. Approved a position statement developed by the Committee on Psychiatry and the Law, at the request of the Assembly: "Position Statement on Involuntary Hospitalization of the Mentally Ill (Revised)" (Bd., Dec. '72).

7. Approved the "Position Statement on College Mental Health," as recommended by the Assembly (Ex.C., Feb. '73).

8. Approved the "Position Statement on the Confidentiality of Medical Research Records," as developed by the APA Task Force on the Confidentiality of Medical Research Records and approved by the Assembly (Ex.C., Feb. '73).

9. Approved the "Position Statement on Aging" (Ex.C., Feb '73).

10. Approved an Assembly resolution (from Area V) that insurance carriers utilized by APA be only those who are able to clearly demonstrate high levels of performance in promoting the concept of the insurability of psychiatric illness and in protecting the interests of the patient (Bd., Dec. '72).

11. Approved an Assembly resolution recommending that strong controls be placed on the availability of all types of guns and rifles—with particular consideration to a policy of confiscation of hand weapons—and allowing for safeguards for retention of appropriate weapons by those with clearly defined requirements for such weapons (Bd., Dec. '72).

12. Approved the "Joint Statement on Antisubstitution Laws and Regulations," as requested by AMA. It was planned that the statement be published in a forthcoming issue of *The American Journal of Psychiatry* (Ex.C., Feb. '73).

ANNUAL MEETING

1. Accepted Toronto as the site for the annual meeting in 1977 (May 9–13), with the staff to investigate any deterrents to achievement of this goal, but asked that the option of Dallas be held open as the next desired place (Bd., Dec. '72).

2. Accepted New Orleans as the site for the annual meeting in 1981 (May 10–15) (Bd., Dec. '72).

3. Approved many recommendations of the Committee on Conventions for revision of the *APA Procedure and Policy Manual for Annual Meetings* (Bd., Dec. '72).

4. Approved the recommended schedule for the 1973 annual meeting in Hawaii, with one exception: disapproved eliminating the presidential reception after the opening session (Bd., Dec. '72).

5. Approved revisions in regulations for operation of the

grants and awards program—mainly clarification of existing policy (Bd., Dec. '72).

AWARDS

1. Approved the selection of an outstanding person in the field of continuing education (Raymond Feldman, M.D.) to receive the 1973 Vestermark Award; approved the change in the format for this year as recommended by the Reference Committee; and approved the recommendation that the future format and criteria for the Vestermark Award be studied by the Grants and Awards Committee (Ex.C., Sept. '72).

2. Approved the Nominating Committee's recommendation that qualifications for nomination for the Distinguished Service Award be publicized in *Psychiatric News* and *The American Journal of Psychiatry* (Bd., Dec. '72).

3. Approved broadening the scope of the Distinguished Service Award, to recapture the original 1964 intent to make it "a citation for highly meritorious service to American psychiatry," to be awarded at the annual meeting in those years when such citation is merited; and further specified that the responsibility for selection of candidates remain with the Nominating Committee (Bd., Dec. '72).

4. Approved the Membership Committee's selection of Martin Roth, M.D., Newcastle-on-Tyne, England, as Distinguished Fellow (Bd., Dec. '72).

5. Approved the Membership Committee's selection of George Anthony Vassiliou, M.D., Athens, Greece, as Corresponding Fellow (Bd., Dec. '72).

6. Approved the Membership Committee's selection of Wesley Arthur Pomeroy, LL.B., J.D., Washington, D. C., as Honorary Fellow (Bd., Dec. '72).

BOARD OF TRUSTEES AND EXECUTIVE COMMITTEE

1. Approved Ewald W. Busse, M.D., as a member of the APA Executive Committee (Bd., May '72).

2. Approved Melvin Sabshin, M.D., as a member of the APA Executive Committee (Bd., May '72).

3. Elected Harry H. Brunt, M.D., to fill the unexpired term of Robert W. Gibson, M.D., on the APA Board of Trustees (Bd., May '72).

4. Voted to hold an additional special ad hoc meeting of the Board of Trustees for policy discussions; limited attendance to voting members of the Board; and noted that it would probably be held in February 1973—definite time, site, and program content to be decided later (Ex.C., Sept. '72).

5. Approved inviting the full Board of Trustees to participate in the special February policy meeting and making this meeting a regular instead of ad hoc meeting (Ex.C., Oct. '72).

6. Extended congratulations to the Program Committee for the special policy meeting of the Board of Trustees in Atlanta, Ga., Feb. 2 and 3, 1973 (Bd., Feb. '73).

7. Asked the President to appoint whatever he deems an appropriate number of Board members to a joint committee with members of the Committee on Constitution and By-Laws and the Executive Committee of the Assembly, to study the issues concerning governance of the Association and representation of the membership on the Board of Trustees (Ex.C., Feb. '73).

8. Asked the Committee on Constitution and By-Laws to consider whether representation on the Board of Trustees should be by subspecialty of interest or solely on the basis of geography (Bd., Feb. '73).

9. Approved holding an extra Executive Committee meeting on April 16, 1973, prior to the May 1973 meeting of the Board of Trustees, to hear the reports that normally take up most of the Board's regularly scheduled two-day meeting in May (Bd., Feb. '73).

10. Approved the request that the Executive Committee schedule its meetings often enough to take care of routine matters of APA business, thereby freeing the Board for more substantive matters and to carry out its primary function of formulating and implementing the policies of the Association (Bd., Feb. '73).

ASSEMBLY

1. Approved the petition for the establishment of a district branch in New Mexico, to be known as the New Mexico Psychiatric Association (Ex.C., June '72).

2. Received the resolution of the Assembly requesting establishment of a research project to study the development of care of the mentally ill by the private sector of psychiatry, and asked that the Assembly be informed as to what direct and pertinent action is being taken at the present time relevant to this matter (Ex.C., June '72).

3. Authorized the Executive Committee of the Assembly to appoint an assembly delegate as a member to attend meetings of each council, to improve communication between the Assembly and the Reference Committee (Bd., Feb. '73).

4. Approved in principle the policy of transmitting Reference Committee reports of the councils simultaneously to the Assembly and the Board of Trustees, to minimize delay in obtaining reactions to reports. Recognizing that this may sometimes be an unmanageable procedure, the Board asked that it be implemented whenever feasible (Bd., Feb. '73).

5. Encouraged the Assembly to ask district branches to function in an advocacy role in their own local areas and to work in conjunction with other consumer advocate bodies (Bd., Feb. '73).

6. Approved the recommendation that the Assembly's Executive Committee liaison appointee to the Council on Internal Organization be responsible for collaboration between the Assembly and the Committee of Residents (Ex.C., Feb. '73).

7. Accepted the Assembly Executive Committee's recommendation to approve an amendment to Article IX, Section 7, of the *Procedural Code*, to give the officers and voting members of the Board of Trustees one vote each, inasmuch as they represent the total membership of the Association (Ex.C., Feb. '73).

8. Rescinded the action (immediately above) taken by the Executive Committee on February 23, 1973, noting that it was doubtful that the Board should vote in this situation in view of its constitutional power to review actions (Ex.C., Apr. '73).

COUNCILS, COMMITTEES, TASK FORCES, AND COMMISSIONS

1. Accepted the recommendation that a task force be established for review of APA *Standards for Psychiatric Facilities*, with priority given to those standards relevant to the Alabama court decision concerning right to treatment (Ex.C., June '72).

2. Approved the request by the chairman of the Council on Internal Organization that his group have available the cost analysis information on the physicians' liability study for further discussion at the October meetings, and left it tabled for the time being (Ex.C., Sept. '72).

3. Terminated two committees: Committee on Rehabilitation and Committee on Psychiatry and Social Work (Bd., Dec. '72).

4. Approved replacing the current Commission on Manpower (scheduled to terminate in May 1973) with an advisory group to the Division of Manpower Research and Development; for purposes of administration and funding the group will be assigned to the Council on Mental Health Services (Bd., Dec. '72).

5. Approved replacing the current Task Force of Residents (scheduled to terminate in May 1973) with a Committee of Residents (or young members), to be assigned to the Council on Internal Organization and to work collaboratively with appropriate components of the Assembly (Bd., Dec. '72).

6. Instructed the Reference Committee to develop before May a structured form for use in delineating the objectives, time limitations, and procedures for achieving the task assigned to each task force, committee, and commission of APA (Bd., Feb. '73).

7. Extended the Commission on Childhood and Adolescence for three years, until May 1976 (Ex.C., Feb. '73).

8. Extended the Commission on Drug Abuse for three years, until May 1976 (Ex.C., Feb. '73).

9. Approved continuance of observer/consultant appointments to each council, with tenure not to exceed five years and possibly to be less than that, to allow for more appointments (Ex.C., Feb. '73).

10. Approved the Assembly's recommendation that final action on *The Principles of Medical Ethics with Annotations Especially Applicable to Psychiatry* be delayed until the May meeting of the Board of Trustees, and asked that in the interim suggested changes (by the Board at this meeting and those subsequently made by district branches and area councils) be reported to the Assembly Executive Committee in February, for recommendation back to the Board of Trustees in May 1973 (Bd., Dec. '72).

11. Approved the proposed policy for maintaining ethical records and asked that legal counsel advise on the period records should be retained before old files are destroyed (Ex.C., Feb. '73).

12. Accepted the Nominating Committee's slate of nominees for officers and trustees for the 1973 APA election and approved the committee's selection for the recipient of the Distinguished Service Award (Bd., Dec. '72).

13. Approved the recommendations of the Committee on Constitution and By-Laws with regard to tightening up the procedures for forming the Nominating Committee from panels presented by the area councils (Bd., Dec. '72).

14. Approved the Nominating Committee's recommendation that a confidential historical file be compiled and maintained in the central office for the continuing guidance of future Nominating Committees (Bd., Dec. '72).

15. Approved the recommendation that area councils publicize the methods of choosing Nominating Committee members, so that members may know their obligations prior to the Nominating Committee's meeting (Ex.C., Feb. '73).

16. Approved continuation of the Ad Hoc Committee on Election Procedures and the Ad Hoc Committee to Study Use of Psychiatric Facilities for Commitment of Political Dissenters for one more year (Bd., May '72).

17. Authorized the Ad Hoc Committee to Study Use of Psychiatric Facilities for Commitment of Political Dissenters to seek necessary funds to finance a project of seeking out and researching examples of specific problems for study (Ex.C., June '72).

18. Approved changing the name of the Ad Hoc Committee to Study Use of Psychiatric Facilities for Commitment of Political Dissenters to that of Ad Hoc Committee to Study Conflicts Inherent in the Therapeutic and Institutional Roles of Psychiatry, but urged constraint in the focus of the mission (Ex.C., Sept. '72).

19. Authorized $2,000 from the pooled balance in Council funds to help finance four proposed meetings this year of the Ad Hoc Committee to Study Conflicts Inherent in the Therapeutic and Institutional Roles of Psychiatry, and recommended that the committee use $2,000 of its grant money for any additional money needed, instead of hiring a principal investigator immediately (Ex.C., Sept. '72).

20. On recommendation of the chairman, disbanded the Ad Hoc Committee to Study Conflicts Inherent in the Therapeutic and Institutional Roles of Psychiatry and requested the Council on Research and Development to appoint a task force to consider the whole matter (Bd., Feb. '73).

21. Authorized the Medical Director to negotiate with the Grant Foundation for payment of debts incurred by the Ad Hoc Committee to Study Conflicts Inherent in the Therapeutic and Institutional Roles of Psychiatry (Bd., Feb. '73).

CONSTITUTION AND BY-LAWS

1. Approved the recommendation of the Committee on Constitution and By-Laws that both the Secretary and Treasurer be elected for two-year terms (in alternate years) and that they be allowed to succeed themselves in office (Bd., Dec. '72).

2. Rejected the recommendation of the Committee on Constitution and By-Laws to eliminate the offices of Vice-President, but favored their terms being increased from one to two years, with elections in alternate years (Bd., Dec. '72).

3. Recommended to the Committee on Constitution and By-Laws that the Trustee-at-Large position be retained (Bd., Dec. '72).

4. Approved the recommendation of the Committee on Constitution and By-Laws that it be mandatory for members to participate in continuing education programs, in accordance with standards to be set by the Association (Bd., Dec. '72).

5. Reaffirmed the position that Vice-Presidents be elected for two-year terms, taking office in alternate years. It was further decided that in order to activate this system if adopted, the candidate receiving the larger number of votes in the first election would be the first two-year Vice-President (Ex.C., Feb. '73).

6. Voted to retain the Trustee-at-Large position on the Board of Trustees (Ex.C., Feb. '73).

7. Voted to retain one Trustee from each designated area of APA—as presently provided in the Constitution—on the Board of Trustees (Ex.C., Feb. '73).

8. Voted to retain a three-year term of office for area Trustees on the Board of Trustees (Ex.C., Feb. '73).

9. Favored retaining the status quo on Past Presidents—that their tenure on the Board of Trustees remain unchanged (Ex.C., Feb. '73).

LIAISON WITH OTHER ORGANIZATIONS

1. Nominated Milton Greenblatt, M.D., for another four-year term as APA director on the American Board of Psychiatry and Neurology, Inc. (Bd., May '72).

2. Nominated Marc Hollender, M.D., as a director on the American Board of Psychiatry and Neurology, Inc., to fill the unexpired term of Lester Rudy, M.D., who assumed the post of executive secretary-treasurer of the ABPN (Ex.C., June '72).

3. Approved a recommendation that APA again request the American Board of Psychiatry and Neurology, Inc., to consider

responsibility for certification in administrative psychiatry (Bd., Dec. '72).

4. Noted and approved forwarding without comment two suggestions of the Council on Medical Education and Career Development regarding consumer representation on the American Board of Psychiatry and Neurology, Inc. (Bd., Dec. '72).

5. Approved conveying without comment the recommendation of the Council on Medical Education and Career Development that training in drug abuse and alcoholism be made a requirement of all residency training programs (Bd., Dec. '72).

6. Approved the suggestion from the American Board of Psychiatry and Neurology, Inc., that Part I, the written examination, may be taken following residency training and that the oral examination may be taken two years later (Ex.C., Feb. '73).

7. Authorized the Medical Director to develop a temporary mechanism for recommending to the AMA accreditation of such allied health workers as corrective therapists, art therapists, and mental health technicians (Ex.C., June '72).

8. Authorized APA headquarters to act as resident agent for the World Psychiatric Association in the District of Columbia, upon written request from the president and the board (or equivalent body) of that group to do so (Ex.C., June '72).

9. Approved the constitution of the Inter-American Council on Psychiatric Associations as submitted (Ex.C., June '72).

10. Approved sending an APA representative to participate in the planning and project proposal of the National Council of Community Mental Health Centers, and authorized funds for his attendance at the meetings (Ex.C., Sept. '72).

11. Approved collaboration with the Royal College of Psychiatrists in a medical education project via closed-circuit television (Ex.C., Sept. '72).

12. Requested the Medical Director to explore a possible basis for affiliation in some form with the American Board of Qualification in Electroencephalography (Ex.C., Feb. '73).

13. Authorized the Medical Director to invite the People's Republic of China to send a representative to participate in any appropriate APA annual meeting—possibly Hawaii in 1973 or Detroit in 1974 (Ex.C., Feb. '73).

OTHER

1. Authorized a telegram to the New York Assembly opposing the separation of mental health from mental hygiene in New York State (Bd., May '72).

2. Received the preliminary report on the member motivation study, with the proviso that the Trustees receive whatever else Prof. Laurence Williams may have in the way of information, and voted to take no further action to extend the study at this time (Ex.C., Sept. '72).

3. Accepted with pleasure the gift from the Gralnick Foundation of a portrait of Austin Davies (Bd., Dec. '72).

4. Approved and endorsed the *AJP* Editorial Board's nominations for three new members: Drs. H. Keith H. Brodie of California, John M. Davis of Tennessee, and Rebecca Z. Solomon of Connecticut (Bd., Dec. '72).

5. Approved the Medical Director's absence from headquarters for approximately four weeks in order to participate in a trip by a 15-member delegation to the People's Republic of China (Ex.C., Feb. '73).

6. Authorized the Task Force of Residents' use of a column in *Psychiatric News*, with the understanding that it be in conformance with APA editorial policy (Ex.C., June '72).

7. Reiterated the request that ways be found to implement the action of the Board of Trustees in its April 29–30, 1972, meeting to increase the function and personnel of the central office's Government Relations Section (Bd., Feb. '73).

8. Requested a study of the feasibility of establishing an office of consumer advocacy or education on the order of the Physician Education Project, with an advisory committee to work with it, and asked for a report at the May 1973 meeting of the Board of Trustees (Bd., Feb. '73).

9. Recommended that the Council on Medical Education and Career Development study the physiomedical aspects of psychiatry and ways in which the residency may be modified (Ex.C., Feb. '73).

10. Approved in principle the new professional liability insurance program for APA members, to be administered by the Joseph A. Britton Agency, subject to approval of the final policy by APA legal counsel, in collaboration with the Committee on Insurance (Ex.C., June '72).

11. Approved three recommendations of the Committee on Member Insurance and Retirement, providing that: 1) committee members be retained for more than one term; 2) authority be given the committee to invite an occasional consultant versed in the malpractice situation; and 3) authority be given the APA President to appoint additional members to the committee if the work load warrants it (Bd., Dec. '72).

12. Considered the resolution on the California confidentiality case involving Dr. George R. Caesar and defeated a motion to donate $2,500 in support of an appeal to the Appellate Court (Bd., May '72).

13. Unanimously disapproved a general policy of financial participation in the defense of psychiatrists who become involved in cases to protect patients' rights of confidentiality (Ex.C., June '72).

14. Approved joining in amicus curiae briefs in the case of *Wyatt v. Stickney* (right to treatment) (Bd., Dec. '72).

15. Validated an affirmative vote in a conference call of March 6, 1973, that APA should file an amicus curiae brief in the case of *Anonymous v. Rogers* (confidentiality of medical records) (Ex.C., Apr. '73).

16. Directed the Council on Medical Education and Career Development to study Dr. E.W. Busse's recommendation for participation in continuing education as a requirement of membership and to bring back a recommendation to the December 1972 meeting of the Board of Trustees (Ex.C., June '72).

17. Approved the Assembly's recommendation that APA devise its own procedure by which district branches can obtain approval for and provide credit to those attending continuing education programs (Bd., Dec. '72).

18. Supported the principle that regional seminars be established in the district branches to teach teachers how best to conduct continuing education programs, if funds are available from the profits of the second self-assessment program (PKSAP-II) (Bd., Dec. '72).

19. Recommended that the Association assume direct and stronger leadership in fostering continuing education (Bd., Feb. '73).

20. Approved in principle establishing a Second Joint Commission on Mental Illness and Health, with the intent that this be a joint venture with other organizations, and approved the establishment of an ad hoc committee—to be assigned to the Council on Mental Health—for preliminary planning of a Second Joint Commission (Bd., Feb. '73).

21. Requested the Reference Committee to commission a study of the current method of reviewing task force reports, with a view to the possibility of establishing a joint publication review committee of the Assembly and the appropriate council and/or Board of Trustees subcommittee (Bd., Feb. '73).

22. Suggested to the Reference Committee the appointment

of a task force to define the terms "mental illness" and "psychiatry" (Bd., Feb. '73).

23. Sent to the Reference Committee a request that the *Diagnostic and Statistical Manual of Mental Disorders (DSM-II)* be revised, that this task be made the responsibility of the Council on Research and Development—with a time limit of two years—and that such a revision be related to the problem-oriented medical record (Bd., Feb. '73).

24. Recommended that whatever terminology is used in defining "functional disability" be subject to classification by diagnostic category and quantitative evaluation in percentages of the degree of functional disability associated with each category (Bd., Feb. '73).

25. Recommended that the Falk Fellowship Program be continued contingent upon funding from the Maurice Falk Medical Fund or other outside resources, and that this year the possibility be explored of an increased subsidy to make it possible for one-year current Falk Fellows (who are eligible and have one more year of residency training) to have a second year of work with the committees—as a trial to see if it adds materially to the value of the program (Ex.C., Feb. '73).

26. Asked the President to appoint an Ad Hoc Committee on Professional Standards Review Organizations—to be assigned to the Council on Mental Health Services—for joint action with a similar committee of the Assembly (Ex.C., Feb. '73).

27. Respectfully rejected Dr. Barton's resignation at this time and asked him to remain on as Medical Director until at least June 1, 1974 (Bd., Dec. '72).

28. Accepted Dr. Barton's recommendations as to procedures for selecting his successor and asked the President to appoint as soon as possible a search committee to survey the job potentials and definitions and promptly consider possible candidates (Bd., Feb. '73).

29. Authorized the Search Committee on Functions and Qualifications of the Medical Director to inquire of each candidate his willingness to have his name submitted. The Executive Committee also approved the Search Committee's wish to accelerate the process of reporting in order that it may finalize its work of selecting appropriate candidates for the Board's consideration in time for an orderly transition in the exchange of Medical Directors (Ex.C., Apr. '73).

30. Accepted the amendment of APA's Retirement Plan Trust on Plan A in order to meet requirements of Revenue Ruling 71-461, and authorized that the revised Retirement Plan Trust be submitted to the Internal Revenue Service for approval (Ex.C., Apr. '73).

ROBERT W. GIBSON, M.D.

Report of the Treasurer

GENERAL: Once again the auditors are still at work on their annual review of the Association's fiscal accounts. As a consequence, the report given here, at the time of the annual meeting, is based on unofficial figures derived from the Association's own fiscal accounting records. Although there will be minor changes within accounts, the report does give an analysis of the fiscal status of APA.

INCOME AND EXPENDITURES: The actual expenditures and income for the fiscal year ending March 31, 1973, were $3,125,501.73 for expenditures and $3,674,840.42 for income. Expenditures and income were each budgeted at $3,364,558.00.

BOARD OF TRUSTEES: The Board of Trustees' account operated at a deficit because the Board held an extra meeting this year that had not been projected. I have asked the Budget Committee to review the contributions of APA to national councils and national organizations and to develop a policy for next year's involvement. The Association, in exercising its leadership role, has maintained extensive liaison with many organizations. This expense is paid from the Contingency Fund.

HOUSEKEEPING COMMITTEES: The constitutional committees lived within their budgets largely because the added expense of the Association's ballot counting was managed by an outside agency and was not billed to the Committee of Tellers during the fiscal year that ended March 31, 1973. We must wait and see whether the $10,000 additional cost for this new arrangement meets the organization's needs. Expenditures under this account were increased by the Ethics Committee's holding additional meetings as it struggled to develop ethical guidelines.

COUNCILS: The councils met as often as was required. There were more task forces in operation than ever before in the history of APA. However, all councils lived within their budgets and turned back to the organization approximately $30,500. It is evident that the importance of the councils, committees, and task forces is recognized and that it is possible for essential business of the Association to be transacted within the amounts appropriated.

INTERNAL ORGANIZATION: Pressures on the Medical Director's Office for additional services continue to be received. Although some departments and divisions exceeded their budgets slightly, savings in others more than offset these overages. The Medical Director's Office and the Division of Public Affairs lived within their budgets, as did the Joint Information Service (JIS), the Membership Division, the Administrative Services Division, the Accounting and Fiscal Division, the Division of Manpower Research and Development, the Meeting Management Department, the Assembly of District Branches, and the Minority Group Program Development Department.

PUBLICATIONS: Although *Psychiatric News* exceeded its estimated expenses by over $43,000, it also exceeded the estimated income by over $90,000. It continues to be the favored advertising medium and to operate soundly in the black.

The American Journal of Psychiatry spent approximately $109,000 less than was estimated to be the cost of producing the journal in its new format. However, its earnings were approximately $35,000 less than anticipated. This was due to a decrease in the number of advertising pages carried.

Hospital & Community Psychiatry has greatly improved its format, content, and financial position during the past year. On the expense side it operated with a surplus of over $37,000; its income was more than $24,000 less than anticipated. This is the second year this journal has continued to improve fiscally.

Some APA publications that did exceptionally well during the year were: *Desk Appointment Book; A Psychiatric Glossary; Diagnostic and Statistical Manual of Mental Disorders (DSM-II);* and the JIS publications *Children and Mental Health Centers: Programs, Problems, Prospects* and *The Treatment of Drug Abuse: Programs, Problems, Prospects.* Also doing well are *Health Insurance and Psychiatric Care: Utilization and Cost* and *Prospects and Proposals: Lifetime Learning for Psychiatrists.* The success of these publications helped balance the loss from the publication of many other important documents such as task force reports and data not available elsewhere.

EMPLOYEE BENEFITS: Personnel policies and salary adjustments necessary to keep APA abreast of federal wage scales required adjustments of staff salaries for the cost of living and for the expansion of the pension plan. However, the cost estimates as budgeted were not exceeded.

ANNUAL MEETING: The annual meeting in Dallas, Tex., showed a deficit in income over that budgeted of over $16,500. It also showed an expenditure of nearly $9,000 less than budgeted. It is anticipated that the deficit for the annual meeting in Hawaii may exceed $50,000. Annual meetings are far from self-sufficient fiscally.

INVESTMENTS: Investments in short-term securities amounted to $492,914 at the end of the 1972 fiscal year. At the end of fiscal year 1973 the amount was $481,148, plus insured certificates of deposit of approximately $300,000.

Short-term investments in commercial paper amounted to $881,374 (with a face value of $900,000), giving an overall total of $1,365,522 for short-term investments.

In spite of an uncertain year in the market and declining interest rates, the market's recovery at the end of the year made it possible to show a fair return on our investments.

The Treasurer, Medical Director, and Comptroller have worked closely with APA's investment counselor, Merrill Lynch, Pierce, Fenner, and Smith, to maintain a positive long-term investment outlook in a fluctuating market.

As of March 31, 1972, the investment portfolio showed a market value of $1,113,874. One year later, as of March 31, 1973, the amount was $1,051,703.[1]

This is an edited version of the report presented by the Treasurer at the annual business meeting in Honolulu, Hawaii, May 8, 1973.

[1] The decrease in the market value is due to the sale of stock, and funds were not reinvested.

The institution of an improved billing and reporting procedure last year made it possible for the organization to obtain a reading on late and unpaid dues. As of March 31, 1973, 90.5 percent of the members had paid their dues. The remaining 9.5 percent may be expected to pay within the next few months. Only a very small percentage of the members will fail to do so. The amount paid exceeded budget estimates by $147,000.

As the inflationary spiral continues, as the cost of everything we do expands, and as the activities and interests of the Association continue to require more support, the cost of operating the Association will naturally increase. Coupled with this will be a greater problem in securing grants, which have in the past represented a significant portion of the total budget of the Association.

Although we have been able to develop a surplus of $560,000 during this fiscal year by carefully controlling expenditures and collecting more dues than anticipated, next year's budget may require a raise in dues in a pattern consistent with the inflationary spiral. The Budget Committee will grapple with this problem when it meets in the fall.

AMERICAN PSYCHIATRIC MUSEUM ASSOCIATION, INC.: During the 1973 fiscal year, $135,000 was advanced by the Board of Trustees to the American Psychiatric Museum Association, Inc. Official notes were received from the Museum's Board of Directors to cover this amount.

Friends of the Museum has been organized and has contributed approximately $3,000 for special purposes of the Museum. No significant bequests, gifts, or grants have been forthcoming to operate this activity. Loans from APA continue to be its principal source of revenue.

This is my last report as your Treasurer. I am grateful to the members, the Assembly of District Branches, and the Board of Trustees for their support and understanding during these many years I have served you as chairman of the Budget Committee and as Treasurer. I leave my office with a sense of pride in the achievements of an increase in the fiscal resources of the Association and a sound fiscal position.

HAYDEN H. DONAHUE, M.D.

Report of the Medical Director

IN THIS MY TENTH REPORT I propose to sketch some of the ways in which your headquarters staff supports the work of the Association. The focus will be on the work done in the fiscal year just concluded and the problems that must be faced in the next few years. The staff joins you, the members, in the anticipation of a new era of progress under new officers and new APA staff leadership.

ADMINISTRATION

Management by objective is an elusive concept in an organization of 20,000 members with multiple goals and differing priorities. A group of members cluster around a shared goal to which they would give priority. Other groups of members may question whether the first group's objective is a legitimate one for the Association. Consensus may not be achievable on some issues. Your staff must hear many voices, receive many suggestions, and be responsive to many publics—members, patients, consumer advocates, concerned citizens, organizations, medical specialty associations, mental health professional and paramedical workers, and local and national governments.

The Association office always responds, sometimes with only an acknowledgment, often with substantive action, occasionally with referral for study, and, when indicated, attempts to negotiate differences.

Your staff answers its thousands of inquiries promptly. Our special talent is to relate the inquiry to the source of information. We struggle to provide material needed as background to decision making by the Assembly and its Executive Committee and by the Board of Trustees and its Executive Committee. Support is also given to councils, committees, task forces, and boards. We have worked hard to earn your confident expectation that the APA headquarters staff will respond appropriately and with integrity.

Extra sessions of the Board of Trustees and the Reference Committee were held this year. Attention was directed to improving organizational efficiency and accelerating the rate of response. An extra meeting of the Executive Committee was scheduled to hear annual reports of APA components. This enabled the Board of Trustees, at its meeting in Hawaii, to devote most of its time to substantive discussion of policy.

FISCAL

Ten years ago the Association operated from three widely separated offices. The editorial office of *The American Journal of Psychiatry* was in Toronto, the Association's business office was in New York, and the headquarters was in Washington. It had limited resources. Today your Association has but one office and by living within its budget has accumulated reserves.

Fiscal control ensures accountability. The wise use of resources has made it possible to set aside enough money in long-term investments to permit the purchase of additional property to expand operations at some future date. Money collected from dues and other income has been put to work in short-term investments timed to be available as bills become due. My goal has been achieved—to have enough reserve to meet obligations and cover six months of operating expense.

The Association has greatly expanded its publication operations. Its periodicals, *The American Journal of Psychiatry* and *Hospital & Community Psychiatry*, appear monthly; *Psychiatric News* is now published twice each month. These publications operate in the black. Task force reports, books, and pamphlets represent an extension of APA's publication efforts. A sizable staff is required to edit and publish these materials. Sound fiscal policies and fair pricing to recover costs result in a nonprofit, no-loss operation. Your Association's fiscal status is sound.

If your demands for service increase, and if the inflationary spiral goes unchecked, greater costs will require new income from dues. The auditors have already suggested further centralization of fiscal systems, computerization of accounting records, and a deputy director for business administration. These suggestions are under study.

RESEARCH AND PROJECTS

The Joint Information Service (APA-National Association for Mental Health) has just published *Mental Health on the Campus*, a field study. Under way are studies of services to children under the age of six and a study of the patients seen in private practice and the duration of their treatment.

An extensive project requiring much staff assistance is being supported by the Smith Kline & French (SKF) Presidential Fund of Dr. Perry Talkington. A monograph on *Gaps in Delivery of Mental Health Services* will be published in the winter.

The SKF Presidential Fund of Dr. Robert Garber supported a study of alternate strategies for funding psychiatric residency training.

The SKF Presidential Fund of Dr. Ewald Busse supported a project whose product is *Mental Illness in Later Life*, a book to be published by APA in May 1973.

Dr. Zigmond Lebensohn and the Medical Director, with Mr. Robert L. Robinson as science writer, have prepared a report on *The Present and Future Importance of Patterns of Private Practice in the Delivery of Mental Health Services*, based on a task force study some two years ago.

The Manpower Research and Development Division has completed its study of the 1970–1971 APA census of psychiatrists, a study of academic resources for training in psychiatry, and a survey of all residents in psychiatry. A new *Descriptive Directory of Psychiatric Training Programs in the United States, 1972–73* was published this month and is now available.

A study of foreign medical graduates in public institutions is nearing completion, and it is possible that a study of Diplomates of the American Board of Psychiatry and Neurology, Inc., may be undertaken shortly.

The computer system was redesigned this year to make access to information easier and retrieval less costly.

Dr. Lee Gurel is the new director of the Manpower Re-

This is an edited version of the report presented by the Medical Director at the annual business meeting in Honolulu, Hawaii, May 8, 1973.

search and Development Division.

A new Minority Group Program Development Department was established at APA headquarters in the fall of 1972, with Dr. Elvin Mackey as its director.

PUBLIC AFFAIRS

The image of psychiatry has eroded as a consequence of blasts from within and without our membership. Mr. Robert L. Robinson (who had his 25th anniversary as Director of Public Affairs for APA this year) presented an eloquent paper on the criticisms of psychiatry at the meeting of the American College of Psychiatrists in January 1973. It will be published in the proceedings of that meeting. It will also form the basis for further study at the Past Presidents' policy seminar during this annual meeting. Psychiatrists, unlike their nonpsychiatrist medical colleagues, have a propensity for self-flagellation in public. If we are to improve our public image, we need to study our own behavior.

The Public Affairs Division produces the program book for the annual meeting and the book of summaries of the presentations made. It produces the popular and useful *Desk Appointment Book* and edits APA reports and books. This year it published a summary pamphlet of all APA position statements.

Psychiatric News, edited by Mr. Robinson, has grown to be the principal medium of information on newsworthy events of national interest to the field of psychiatry.

Very prominent in the public eye is the Government Relations Section. Staff members assemble information for statements describing APA's stand on issues that concern the field of psychiatry to be presented to committees and individual members of Congress. This section also works with coalitions and liaison groups to share information and plan for coordinated action. In March of this year a second Government Operations Institute was held, attended by area and district branch legislative representatives. A network of legislative representatives has been formed to mobilize public support for the national mental health programs and, as the scene shifts to revenue sharing, for support of the programs at the state and local levels.

MAKE A JOYFUL NOISE

Your voice is but a whisper amid the babble of the multitude when you speak alone. If your brother members in the Association add their voices to yours, you can be heard. If all of medicine speaks with one voice, and if the mental health professions speak together, if patients, consumers, and the vast public join in, it will indeed make a joyful noise. That great voice will be heard and the monuments in Washington will tremble. We, the staff, cannot protect you from the "blessings" of the future. Speak up! It is your collective voice that will help shape the world about you.

WALTER E. BARTON, M.D.

Report of the Speaker

EACH ADMINISTRATION of the Assembly has had its own priorities. This administration has been no exception. For the past year emphasis has been placed on the development of peer review standards and on mechanisms for evaluating psychiatric services, continuing education, and the involvement of younger members in the Association. These are all relatively new concerns for the Assembly and the Association, and they have developed their importance not, unfortunately, on their own merits, but as a response to external pressures.

This type of reactivity—in contrast to initiative—has been the perennial custom of organized medicine, possibly to its detriment. The admonition "If you don't do it for yourselves, somebody else will do it for you" has stimulated the profession ever since federal authorities and the consumer began to take an active interest in the health field. As a result, the Assembly, in concert with other elements of the Association, has become more politicized and, by extension, defensive than heretofore. I cannot say whether this fact is good or bad, but I can report to you what the Assembly has done in response to the implied demands of our sociopolitical ambiance.

The Assembly has approved publication of the task force report on peer review and has insisted that each district branch have a functioning committee and a written plan for psychiatric peer review by April 1 of this year. At the present time, 18 district branches have submitted such reports. We hope that our membership will be prepared to help implement the activities proposed in the Bennett Amendment.

Through the Speaker-Elect of the Assembly, who served as chairman of the Committee on Constitution and By-Laws, an amendment to the Constitution has been proposed and approved by the Board requiring each member to submit annually proof of continuing education as a condition of membership. Each district branch has a committee on continuing education preparing programs that will be subject to approval by APA's Office of Continuing Education.

We have been less successful regarding the involvement of younger members in the Association. From over 5,000 residents in psychiatry, the Association has been able to attract fewer than 600 into participating membership in spite of an active recruiting campaign conducted by the Assembly, the central office, and the Division of Public Affairs, which has prepared an excellent recruiting pamphlet. A Committee of Residents, attached to the Council on Internal Affairs, has now been activated, with liaison with the Assembly. Perhaps this committee can provide insight into the unanswered question of why younger psychiatrists do not affiliate earlier.

All three of these priorities have had their basis in political pressures and reflect the increasing politicization of the Association, both from within and outside its ranks.

Externally, we have been beset by reduced federal support for a variety of mental health programs, the imminence of national health insurance (NHI) proposals that uniformly discriminate against consumers of mental health services, and a strong antipsychiatric bias based on mistrust of the profession, economic caution, and lack of appropriate information regarding psychiatrists and their spheres of operation. The requirement to justify the need for professional services, already mandated in the Professional Standards Review Organization (PSRO) legislation, will increase unless the doubt and mistrust of the authenticity and reliability of psychiatric services are alleviated.

When the Association has attempted to prolong federal support of manpower training, the following objection has been raised: "Why should taxpayers' dollars be spent to train psychiatrists who go into private practice and get rich?" If one points out that the median income of psychiatrists is less than $36,000 annually, legislators readily answer that this fact is due to the high employment of psychiatrists in state hospitals. This type of circular reasoning is difficult to counter. We are frequently met by such questions as: "What does a psychiatrist do?"; "Does psychiatry cure anybody?"; "Why is it so expensive?"

The Assembly has made attempts to meet these challenges by appointing a task force to develop a report on psychiatrists' areas of competence, defining their role and establishing their boundaries. This task force will attempt to delineate the professional capability of our members and to explicate the common denominator of professionalism in the face of marked fragmentation of modalities and so-called schools of psychiatry within the profession.

The district branches quite successfully mounted a strong mail and telephone campaign to restore federal training funds, only to have the allocated funds impounded by the Administration. In addition, legislative representatives of the district branches have attended two institutes on government relations for the purpose of forming a forceful network of legislative advocates for mental health concerns throughout the country. The response to pressures for social reform has resulted in a policy statement on homicide prevention via gun control, a statement concerning the rights of patients subject to involuntary hospitalization, and a Task Force on Sexual Stereotypy.

During the present meeting of the Assembly, a resolution for expanding the legislative influence of the Association through the establishment of a separate office of government relations was introduced. It is clear that the Assembly, if not the entire Association, has been impelled to put political concerns higher on its priority list than other issues.

From within the Association, the Assembly, no less than other elements of the organization, has been subject to criticism by fellow members—all the way from those who would destroy the present structure of APA and rebuild it on another model, through those who wish to convert the Association into a totally socially activist organization, to those—perhaps more clinically oriented—who declare that schizophrenia is not to be considered a disease process and that homosexuality is.

In the face of these internal stresses, the Assembly has remained an island of stability and continuity, able, by its very nature and at the risk of sometimes appearing conservative rather than deliberative, to maintain a course of evolutionary progress and responsibility in fulfilling its role as a legislative interface between the membership and the APA administration.

As the outgoing Speaker of the Assembly I feel privileged to speak about the course of future concerns for the Assembly. First, I feel that the Assembly now has a constitutional right to speak for the membership of the entire Association and has the

This is an edited version of the report presented by the Speaker of the Assembly of District Branches at the annual business meeting in Honolulu, Hawaii, May 8, 1973.

channels for discerning the tenor of the membership's attitudes. Second, if the Assembly is to assume a role of legislative advocacy for progress in mental health programs, it must assume a stance of responsibility. If we are to go before the legislatures and campaign for a portion of the taxpayers' dollars in return for better service to the population as a whole, we must be willing to assume our share of the load. If we wish to train more psychiatrists for the welfare of the nation at the expense of the nation, then our resources must reflect our rhetoric, our distributive mobility must match our motivation; and our declarations must derive from our deeds.

The Assembly has had a Task Force on Delivery of Mental Health Services for over three years. It must now turn its attention somewhat away from legislative concerns such as NHI, PSROs, and other legislative proposals and begin developing plans for easy accessibility to mental health services by all elements of our population, with assurance that consumers from all socioeconomic levels will receive an equally high quality of care. This will require cooperative planning with other mental health professionals for meeting the needs of an anxiety-ridden populace.

We have a Committee on Public Information that can easily be converted into a Committee on Public Education. Rights of patients must be matched by patient responsibility. Without appropriate education, patients cannot exercise their responsibilities or demand their rights. One cannot legitimately demand good health as a right; one can demand good medical care. In spite of the fact that psychiatrists allege they can determine what is good psychiatric care, they have been the last to assume advocacy for the consumer, leaving this important task to the courts. It is time for the Assembly and the district branches to consider performing this function.

The Assembly has been and is a well-tuned instrument of the membership. Sometimes the constituency has played it with dissonance, most often with harmony. Its capacity for stability and continuity as a representative of the total membership represents a marked asset to the Association. I trust that it will not be allowed to stand idle, like a well-polished Steinway standing decoratively in a living room, but unplayed. Instead I urge you, the instrumentalists, to play it well for the benefit of the membership and for the welfare of the applicants for our services.

JAMES C. JOHNSON, JR.

Report of the Speaker-Elect

THE AMERICAN PSYCHIATRIC ASSOCIATION is an organization of physicians specializing in psychiatry who have associated themselves in the pursuit of certain shared goals. The Association is founded on the implicit assumption that more can be accomplished by acting collectively than could be accomplished by individual action. The purposes of the Association, as set forth in its Constitution, are improvement in the care, treatment, and rehabilitation of the mentally ill, mentally retarded, and emotionally disturbed. The Constitution explains that the Association intends to accomplish this by research, education, standard-setting, and the dissemination of information to allied disciplines and the public. The vitality and viability of the Association is dependent on whether it brings about progress toward these goals—progress that could not have been accomplished by the members acting individually.

The goals are idealistic, and it is apparent that it is the intent of the members that their Association shall be an instrument for the collective expression of this idealism. The Association has been granted the highest form of tax-exempt status, which in actuality is the equivalent of a subsidy by public funds. Because of this the Association has a responsibility to the public as well as its members.

The organizational structure of the Association must therefore provide the means for an active pursuit of these goals and must at the same time provide an opportunity for active participation in the Association by the members.

If the Association is to be an effective instrument for the expression of the idealistic concerns of the members, vicarious participation is not adequate. The members must be able to identify with the Association and identify it as an extension of themselves.

For the individual members to identify with the Association and have a significant voice in its affairs, APA must have a democratic structure, with open elections and officers and a governing body that is accountable and responsive to the wishes of the members. Traditionally the Association has been regarded as having such a structure, but with growth in membership and geographical dispersion after World War II, the Association took on more of the characteristics of a large corporation than of a democratic society. The annual business meeting, which was supposed to be an example of town meeting democracy, became in fact a pro forma endorsement by APA members of the actions of the officers and governing body.

As a result, the distance between the members and governors of the Association gradually increased, and effective contact was lost. The officers and governing body were dedicated to the goals of the Association and acted effectively to capitalize on the increased interest in mental health that occurred after World War II. Unfortunately, however, the members were to a large extent unaware of these accomplishments or of the role of their Association in bringing about productive change, such as the establishment of NIMH and the Joint Commission on Mental Illness and Health, or APA's support for education in psychiatry and related disciplines.

This is an edited version of the report presented by the Speaker-Elect of the Assembly of District Branches at the annual business meeting in Honolulu, Hawaii, May 8, 1973.

The committees of the Association were the only means open to members for active participation, but even though the number of committees increased to a fantastic and unwieldy number, only a small fraction of the total membership was involved.

A number of developments can be attributed in part at least to this loss of contact with and alienation of individual members. Repeated major and minor palace revolutions occurred in which one establishment was partially or completely replaced by another. A major concern of the Airlie House Conference in the mid sixties was the internal organization of the Association. Some of the recommendations from the conference were clearly in the direction of representative democracy, and the presence of six area Trustees on the Board was a direct result of those recommendations. Recommendations were made for a change to a task-oriented committee structure and for elimination of the multitude of standing committees. The present system of the Reference Committee and councils was a direct result of those recommendations.

Perhaps the most significant example of reaction to the loss of contact and alienation of the members was the development of the Assembly and the district branch system. It was founded just 20 years ago and began an immediate, vigorous growth in both members and influence, a growth that has continued.

This vigorous growth occurred because the Assembly is representative democracy in action, providing an opportunity for the individual member to participate directly in his chapter and district branch and to influence the vote of his representative in the Assembly.

Initially the Assembly did not have any formal role in the Association and was largely ignored by its officers and governing body. It was widely regarded as impotent and was tolerated because of its usefulness in providing a podium for empty oratory as a safety valve to relieve the pressures and tensions that had developed in the membership.

The image and role of the Assembly have gradually changed during these 20 years. Initially, only a small fraction of APA members were members of district branches. Now district branch membership is a requirement for APA membership for all except a small percentage, who are members-at-large under a "grandfather clause."

The officers and governing body have become more and more dependent on the Assembly for contact with the membership. The Assembly serves a vital function in informing members about issues and actions and informing the Board and the officers about prevailing opinion and sentiment among the members.

The Assembly has a pyramidal structure. The delegates in each of the six geographical areas are organized into area councils headed by an area representative and deputy area representative. These 12 officers, together with the officers of the Assembly, make up the Executive Committee of the Assembly. The Executive Committee is authorized to act for the Assembly when it is not in session.

Significant increases in power and influence were granted to the Assembly in the 1968 and 1972 revisions of the Constitution and By-Laws.

The Speaker became an ex-officio member of the Board and its Executive Committee. The Speaker-Elect is now an ex-officio member of the Reference Committee.

Perhaps the most significant change was authorization for the Assembly to act for all of the membership at the annual meeting in receiving for approval or disapproval the reports of actions by the Board and the officers during the preceding year.

In addition, the Assembly was given authority to call for a referendum of the membership on any action of the Board or its Executive Committee that the Assembly regarded as being contrary to the best interests of the Association or the wishes of the membership.

Additional changes are under way that will become operative during this coming year. This year's budget includes funds for an additional area council meeting. This will make it possible for each area council to meet four times during the year and will provide the potential for much-needed improvement in the legislative function of the Assembly.

A very significant development was approval by the Board of the appointment of a representative from the Assembly Executive Committee to sit with each council.

Investigation, study, and planning by the councils and the Reference Committee are the basis for the policies, position statements, and programs expressing the goals of the Association.

This new relationship between the Assembly and the councils will bring together the two elements in the Association that are essential to its viability—effective participation by the membership and progress toward the goals of the Association.

The Assembly has now reached adulthood, but this new status carries with it great responsibility. Continuing study of, refining, and improving the functioning of the Assembly are needed if it is to adequately discharge its responsibility to the members, the Association, and the public.

WARREN S. WILLIAMS, M.D.

1973 Annual Report of the American Board of Psychiatry and Neurology, Inc.

OFFICERS AND MEMBERS OF THE BOARD

AT ITS ANNUAL MEETING in October 1972 the Board elected the following people as its officers: Dr. Samuel A. Trufant, President; Dr. Harvey J. Tompkins, Vice-President; and Dr. Robert L. Stubblefield, Secretary-Treasurer.

The following members were elected to succeed themselves: Dr. Milton Greenblatt and Dr. David B. Clark. Dr. Robert J. Joynt was elected to succeed Dr. Arnold P. Friedman, who completed his second term of four years on January 1, 1973. Dr. Marc H. Hollender was elected to succeed Dr. Lester H. Rudy, who resigned his Directorship May 31, 1972, to assume the position of Executive Secretary-Treasurer.

The 1973 Directors of the American Board of Psychiatry and Neurology, Inc., are as follows:

Appointed by the American Medical Association: Dr. Clark H. Millikan* (term expires December 1974), Dr. Robert L. Stubblefield* (term expires December 1975), Dr. Robert J. Joynt (term expires December 1976), and Dr. Shervert Frazier* (term expires December 1973).

Appointed by the American Neurological Association: Dr. Samuel A. Trufant* (term expires December 1974), Dr. William M. Landau* (term expires December 1975), Dr. David B. Clark* (term expires December 1976), and Dr. Thomas A. Farmer (term expires December 1973).

Appointed by the American Psychiatric Association: Dr. Chester M. Pierce (term expires December 1974), Dr. Harvey J. Tompkins* (term expires December 1975), Dr. Milton Greenblatt* (term expires December 1976), and Dr. Marc H. Hollender (term expires December 1973).

EXAMINATIONS

Effective July 1, 1973, the American Board of Psychiatry and Neurology, Inc., will accept an application for certificate immediately after the applicant completes his training program, provided the following requirements are met:

1. The applicant completes his training requirement no later than June 30 preceding the date of the Part I examination to which he is seeking admission.
2. The applicant files an application on the official form after July 1 of the year he completes training, and the application is received in the executive office no later than October 31 preceding the date of the Part I examination.

A candidate who elects this option will be required to take the next scheduled Part I following the date he is accepted for examination. Failure to do so will require reapplication and payment of the application fee. A candidate who passes Part I will be scheduled for Part II upon receiving credit for two years of experience.

This is an edited version of the report presented by the American Board of Psychiatry and Neurology, Inc., to the American Psychiatric Association, May 1973.

*These Directors are serving their second term of four years and are not eligible for reappointment.

TABLE 1
Number Declared Eligible and Notified for Part I Written Examination on April 23, 1973

Item	Psychiatry	Neurology	Total
Number declared eligible and notified	1,665	334	1,999
Number who declined or withdrew	588	30	618
Number remaining for written examination as of April 9, 1973	1,077	304	1,381

Part I

For the Part I examination given on April 17, 1972, 779 psychiatrists were tested; 500 (64.2 percent) passed and 279 (35.8 percent) failed. Of the 186 neurologists tested, 121 (65.1 percent) passed and 65 (34.9 percent) failed.

For the 1973 Part I examination, 1,077 psychiatrists and 304 neurologists have accepted assignment. See table 1 for the number of candidates declared eligible and notified for Part I in 1973, and table 2 for a comparison of these figures with other years.

Part II

There were 545 candidates present at the Part II examination given in St. Louis, Mo., on October 2–3, 1972. This was the largest examination the Board has administered. See tables 3 and 4 for the statistics for this examination and for the Part II given in Boston, Mass., on April 2–3, 1973.

Two large examinations are planned for the Part II 1973–1974 examining year. One examination will be given in Chicago on October 1–2, 1973, and a second one in Los Angeles on April 1–2, 1974. In the future the Board plans to maintain a schedule of two Part II examinations a year.

CHILD PSYCHIATRY

Members of the current Committee on Certification in Child Psychiatry are: Dr. H. Donald Dunton, Chairman; Dr. John F.

McDermott, Vice-Chairman; Dr. Barbara Fish, Secretary-Treasurer; Dr. Stuart M. Finch; Dr. Jeanne Spurlock; Dr. Richard S. Ward; and Dr. Richard W. Olmsted, American Board of Pediatrics.

At its meeting in Madison, Wis., in March 1973, the Committee voted to increase application and examination fees. The following fee schedule became effective April 1, 1973: application fee, $150; oral examination, $200; oral reexamination-failure, $200; and oral reexamination-condition, $150.

In March 1973 the Committee conducted its annual examination. Of the 96 candidates examined, 55 were certified in child psychiatry.

The Committee received an award of $50,000 from the Grant Foundation to study certification in child psychiatry.

AMERICAN BOARD OF MEDICAL SPECIALTIES

The Board has a more forceful role in the American Board of Medical Specialties. Dr. Rudy has been appointed to the Committee on Certification and Recertification and the Committee for Long-Range Planning.

Proposed Amendments to the Constitution and By-Laws

The amended Constitution and By-Laws became effective in May 1973. The amendments that follow are identified as being proposed either by petition or by the Committee on Constitution and By-Laws. These proposals were received within the 60-day deadline before the annual meeting and were presented at the annual business session. They will appear on the ballot in March 1974.

Note: The following changes in type style indicate the following proposed changes in the Constitution and By-Laws: 1) underlining = proposed additions to the Constitution and By-Laws (e.g., "by resolution of the Assembly"); and 2) brackets = proposed deletions from the Constitution and By-Laws (e.g., "may originate [either] . . ."); Articles and sections of the Constitution and chapters and sections of the By-Laws that are not listed here have not been subject to any proposed changes.

Proposed Amendment to the Constitution

ARTICLE IX. AMENDMENTS

Section 1 (proposed by petition)

Proposals to amend the Constitution may originate either (a) by a petition signed by [200] 50 or more voting members, (b) by resolution of the Board, or (c) by resolution of the Assembly. A statement from those initiating the amendment setting forth the reasons for the action and a statement from the Board shall accompany the ballot.

Proposed Amendments to the By-Laws

CHAPTER ONE. MEMBERS

Section 3 (proposed by committee)

To maintain membership in good standing all members are required to participate in continuing education according to the standards of the American Psychiatric Association.

Sections [3] through [11] renumbered 4 through 12.

Section 6 (proposed by petition)

Fellows shall have been General Members for at least five years and shall have made a significant contribution to the field of psychiatry. At its discretion the Board, upon recommendation of the Membership Committee, may waive the requirement for five years as a General Member. The criteria and procedures for selection and nomination of General Members for Fellowship shall be established by the Board and the Membership Committee and shall apply uniformly for all District Branches.

CHAPTER FOUR. OFFICERS

Section 7 (proposed by committee)

[The Officers of the Association shall hold office for one year.] The President and Vice-Presidents are ineligible for re-election to the same office. The President shall hold office for one year. The Vice-Presidents shall be elected in alternate years, and each shall hold office for two years. The Secretary and Treasurer shall be elected in alternate years, and each shall hold office for two years.

Section 8 (c) (proposed by petition)

If any other office becomes vacant, the Board shall select [a Fellow] any voting member of the Association to fill that office for the remainder of the term.

CHAPTER SIX. COUNCILS, COMMITTEES, BOARDS, AND OTHER ORGANIZATIONAL ENTITIES

Section 5 (proposed by committee)

The Nominating Committee shall be appointed by the President within the first 60 days of [each] his term of office and shall be comprised of a representative from each geographical area of the Assembly plus a chairman. Each area council shall propose at least three candidates, and the President shall appoint the members from among those candidates. He may choose any voting member as chairman of the committee. The Committee shall nominate at least two candidates for each office and report its nominations [no later than October 31 of each year.] to the Board by October 1 for immediate dissemination to the members.

CHAPTER EIGHT. PRIVILEGES AND RESPONSIBILITIES

Section 3 (proposed by petition)

[Only Fellows and Life Fellows shall] Any voting member may hold elected office, serve on councils, or serve as chairmen of committees, boards, and commissions.

Section 5 (proposed by petition)

The voting membership may initiate referenda or change an action of the Board by the following procedure: A petition signed by at least [200] 50 voting members shall be submitted to the Secretary no later than January 1 to be voted on in the mail ballot for that year. A statement from the petitioners setting forth the reasons for the reasons for the action and a statement from the Board shall accompany the ballot. A simple majority of 40 percent of the eligible voting members shall be required for approval.

Section 6 (proposed by petition)

Every Fellow, Life Fellow, General Member, Life Member, Associate Member, and Member-in-Training shall pay both dues and assessments as determined by the Board and the District Branches. All other categories of membership shall be exempt from paying dues to both the Association and its District Branches.

CHAPTER NINE. VOTING

Section 1 (proposed by petition)

Any [Fellow or Life Fellow] voting member nominated for office by a petition signed by [200] 50 or more members eligible to vote shall have his name included on the official ballot for the next general election, provided that such petition has been filed with the Secretary before January 1 of the year he would be elected.

CHAPTER ELEVEN. ANNUAL BUSINESS MEETING

Section 1 (proposed by petition)

At a previously announced time during the Annual Meeting, the President of the Association shall convene a business meeting composed of two consecutive sessions: (1) a meeting of the Assembly to act for the membership in receiving a report of the actions of the Board and the reports of the Speaker of the Assembly, the Medical Director, the Treasurer, and the chairmen of the councils and the constitutional committees; and (2) an annual forum for all voting members. Only voting members of the Association may attend this business meeting.

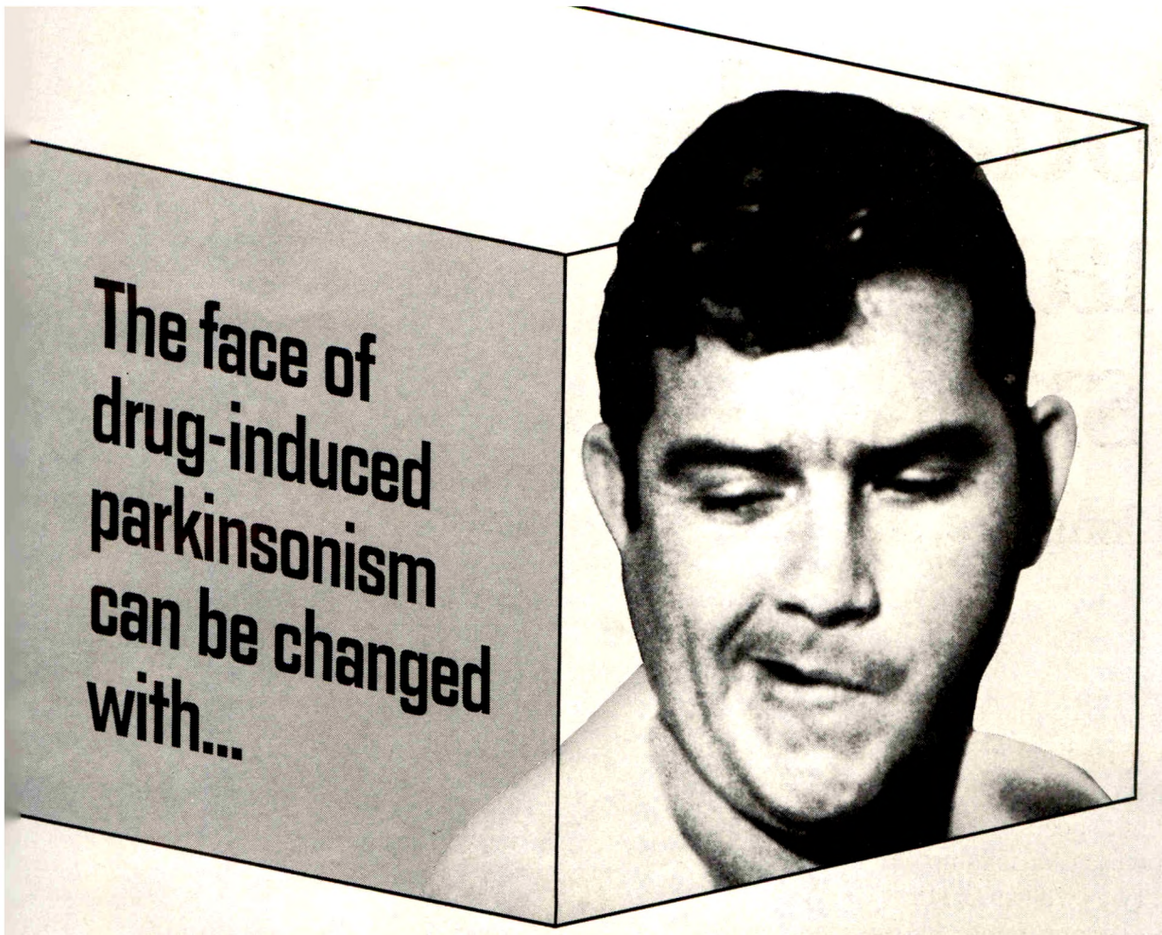
Section 2 (proposed by petition)

The Assembly may vote [to approve or disapprove by majority vote the reported actions but may not reverse an action of the Board except through the process for a referendum as described in Section 6, Chapter Seven of these By-Laws. Only voting members of the Association may attend this business meeting.] by simple majority on any matters before the business meeting except to reverse an action of the Board, which will require a two-thirds majority vote of the Assembly.

CHAPTER TWELVE. ANNUAL FORUM

Section 1 (proposed by petition)

[At a previously announced time following the business meeting the President shall convene an open forum for all members to consider the present and future course of the Association.] After the conclusion of the first session of the business meeting, at a reasonable point within the time allotted for the business meeting as a whole, the President shall convene the annual forum session of the business meeting for all the voting members.



Section 2 (proposed by petition)

[Proposals about the affairs of the Association, including resolutions for referenda, may be introduced and if approved by a majority of the voting members present circulated in the next mail ballot of the Association. A two-thirds majority of the voting members may call for an extraordinary vote, and this shall require a mail ballot to be circulated and reported prior to the fall meeting of the Assembly.] Proposals about the affairs of the Association, and any old or new business, may be introduced and voted on by a two-thirds majority of the voting members present except to reverse an action of the Board or Assembly. To reverse an action of the Board or Assembly, a two-thirds majority of the voting members may call for an extraordinary vote, and this shall require a mail ballot to be circulated and reported prior to the fall meeting of the Assembly. In matters other than a Board or Assembly action, a simple majority of voting members present may initiate the referendum process as described in Section 6, Chapter Seven of these By-Laws.

Section 3 (proposed by petition)

After a referendum is approved by a two-thirds majority of the voting members present, the Board or Executive Committee shall review it to determine whether any conflict with the Constitution and By-Laws or with the legal status or established policy of the Association exists and shall [resolve] formulate an opinion on any such conflicts before it is circulated to the members. The circulated referendum shall carry with it both the opinion of the Board and the opinion of those initiating the referendum.

[Should the Board decide not to circulate any such referenda, a report of the decision and the reasons for it shall be published as expeditiously as possible in a publication of the Association.]

AKINETON®
(biperiden)

- relieves extrapyramidal reactions
- reduces akinesia and rigidity
- combines well with other anti-parkinson agents
- more than ten years of clinical experience

WARNINGS, PRECAUTIONS, ADVERSE REACTIONS: Isolated instances of mental confusion, euphoria, agitation and disturbed behavior have been reported in susceptible patients. Use with caution in manifest glaucoma, prostatism and cardiac arrhythmia. Dry mouth, blurred vision and drowsiness appear infrequently. Some decrease in urinary flow has been noted in a few patients. If gastric irritation occurs, it may be avoided by administering during or after meals. With parenteral administration, mild transient postural hypotension may be evidenced. The only known contraindication is sensitivity to Akineton (biperiden.) DOSAGE: Orally; **Parkinsonism:** 1 tablet, 2 mg., 3 or 4 times daily. **Drug-induced extrapyramidal disorders:** 1 tablet, 2 mg., 1 to 3 times daily. Parenterally: the average adult dose is 2 mg. intramuscularly or intravenously. May be repeated every half-hour until resolution of symptoms is effected, but not more than 4 consecutive doses should be administered in a 24-hour period. SUPPLIED: Tablets—2 mg. (bisected) Akineton HCl. Ampules—1 ml. containing 5 mg. Akineton lactate in an aqueous 1.4% sodium lactate solution.

KNOLL PHARMACEUTICAL COMPANY · WHIPPANY, NEW JERSEY 07981 · TORONTO, CANADA

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD) helps establish early therapeutic rapport

traindications: Known hypersensitivity; acute recovery phase following myocardial rction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe vulsions, and deaths have occurred in patients receiving tricyclic antidepressant and OI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, inimum of 14 days should be allowed to elapse after the latter is discontinued. Protyline HCl should then be initiated cautiously with gradual increase in dosage until imum response is achieved.

nings: May block the antihypertensive effect of guanethidine or similarly acting comnds. May impair mental and/or physical abilities required for the performance of hazard- tasks, such as operating machinery or driving a motor vehicle. Should be used with tion in patients with a history of seizures and, because of its autonomic activity, in ents with a tendency to urinary retention or increased intraocular tension.

hycardia and postural hypotension may occur more frequently than with other antiressant drugs. Should be used with caution in elderly patients and patients with cardiocular disorders; such patients should be observed closely because of the tendency of drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the contion time. Myocardial infarction and stroke have occurred with drugs of this class. rare occasions, hyperthyroid patients or those receiving thyroid medication develop arrhythmias when this drug is given.

ge in Children: Not recommended for use in children because safety and effectiveness ne pediatric age group have not been established.

ge in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, in pregnant women, nursing mothers, or women who may become pregnant requires possible benefits be weighed against possible hazards to mother and child.

cautions: When protriptyline HCl is used to treat the depressive component of schizoenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, ressed patients may experience a shift toward the manic phase; paranoid delusions, n or without associated hostility, may be exaggerated. In any of these circumstances, it be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug currently. Symptoms, such as anxiety or agitation, may be aggravated in overactive gitated patients.

en given with anticholinergic agents or sympathomimetic drugs, including epinephrine nbined with local anesthetics, close supervision and careful adjustment of dosages are uired. May enhance response to alcohol and effects of barbiturates and other CNS ressants. Possibility of suicide in depressed patients remains during treatment and il significant remission occurs; this type of patient should not have easy access to e quantities of the drug. Concurrent administration with electroshock therapy may rease hazards of therapy; such treatment should be limited to patients for whom it is ential. Discontinue drug several days before elective surgery, if possible. Both elevation l lowering of blood sugar levels have been reported.

verse Reactions: *Note:* Included in this listing are a few adverse reactions which have been reported with this specific drug. However, the pharmacologic similarities among tricyclic antidepressant drugs require that each of the reactions be considered when triptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation l anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

diovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, hythmias, heart block, stroke.

chiatric: confusional states (especially in the elderly) with hallucinations, disorienta- n, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightres; hypomania; exacerbation of psychosis.

rological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, mors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG terns, tinnitus.

ticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturnce of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed turition, dilatation of the urinary tract.

ergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exsure to sunlight), edema (general, or of face and tongue), drug fever.

matologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; ombocytopenia.

strointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, matitis, abdominal cramps, black tongue.

docrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; reased or decreased libido, impotence; testicular swelling; elevation or depression of od sugar levels.

er: jaundice (simulating obstructive); altered liver function; weight gain or loss; spiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and gue; headache; parotid swelling; alopecia.

hdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after longed therapy may produce nausea, headache, and malaise.

erdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been orted to reverse the symptoms of amitriptyline poisoning in humans. Animal studies e shown that physostigmine also reverses certain toxic effects of protriptyline, but to sser extent.

w Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit kages of 100 and bottles of 100 and 1000.

more detailed information, consult your MSD representative or see full prescribing information.

addendum

MSD
MERCK SHARP & DOHME

MSD 26 5 mg (orange)

MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

Mental Illness in Later Life

by Ewald W. Busse, M.D.
Eric Pfeiffer, M.D.

A comprehensive, practical guide for the practicing physician about the emotional problems of the aged patient. Included are pragmatic suggestions for interviewing, diagnosis, treatment, and supportive care, with consideration of social, cultural, and psychological factors. A special *Question-and-Answer* section is a valuable supplement.

"The 12 well written chapters of this book, all by knowledgeable investigators in the field of geriatric mental illness, offer both an overall review of the current status of the field and more detailed information on such specialized topics as the demography of aging, the epidemiology of geriatric mental disorder, diagnostic procedures of the evaluation of brain impairment, social and psychological aspects of mental illness in the aged, insurance coverage for mental illness in later life, organic and functional geriatric mental disorders, physical changes with aging and their relationship to mental functioning, and institutional and ambulatory treatment of the aged mentally ill. The content and approach make the volume appropriate and useful reading both for psychiatrists, who have paid too little attention to the psychiatric problems of the aged, and for social workers, psychologists, nurses, and other personnel who deal with the elderly mentally ill. Pragmatic suggestions are made for interviewing, diagnosis, treatment, and supportive care, and there is adequate emphasis on social, psychologic, and cultural factors. The Question and Answer *section of the book is an especially valuable supplement, especially to readers whose interest is primarily pragmatic."*

We've got a new name

(potassium gluconate-potassium chloride)

(but that's all).

KALYUM™ Liquid (potassium gluconate-potassium chloride), that's our old name. The name you knew us by.

We liked it. After all it's the Latin pronunciation for "potassium." And potassium supplementation is what we're all about.

So why change our name to KOLYUM™ Liquid (potassium gluconate-potassium chloride)?

It just happens that our old name could possibly be mistaken for the name of a large product in another therapeutic category. So we decided to eliminate any chance of confusion by changing *our* name.

But our name is all we changed. Kolyum (new name) is still the same good-tasting cherry flavored potassium supplement you trusted under the name of Kalyum.

So from now on—whenever you want effective potassium supplementation *without sodium and calories*, remember our new name: Kolyum Liquid.

Kolyum Liquid.

Potassium supplementation gets a neat new name.

PRESCRIBING INFORMATION
DESCRIPTION—Each 15 ml tablespoon provides 20 mEq of potassium ion and 3.34 mEq of chloride ion in a sugar free, cherry flavored vehicle. INDICATION—Oral potassium therapy for the prevention and treatment of hypokalemia which may occur secondary to diuretic or corticosteroid administration. May be used in the treatment of cardiac arrhythmias due to digitalis intoxication. CONTRAINDICATIONS—Severe renal impairment with oliguria or azotemia, untreated Addison's disease, adynamia episodica hereditaria, acute dehydration, heat cramps and hyperkalemia from any cause. PRECAUTIONS—Potassium supplements must be administered with caution, since the amount of the deficiency or daily dosage is not accurately known. Frequent checks of the clinical status of the patient, and periodic ECG and/or serum potassium levels should be made. High serum concentrations of potassium ion may cause death through cardiac depression, arrhythmias or arrest. This drug should be used with caution in the presence of cardiac disease. Extreme caution should be used in patients receiving aldosterone antagonists or potassium sparing diuretics. In both cases potassium intoxication might occur. ADVERSE REACTIONS—Nausea, vomiting, diarrhea and abdominal discomfort have been reported. The symptoms and signs of potassium intoxication include paresthesias of the extremities, flaccid paralysis, listlessness, mental confusion, weakness and heaviness of the legs, fall in blood pressure, cardiac arrhythmias and heart block. Hyperkalemia may exhibit the following electrocardiographic abnormalities: disappearance of the P wave, widening and slurring of QRS complex, changes of the S-T segment and tall peaked T waves. DOSAGE—The usual adult dosage is one tablespoonful (15 ml) in one fluid ounce or more of water twice daily. This supplies 40 mEq of potassium ion which is the approximate minimal adult daily requirement, as well as 6.68 mEq of chloride ion. Deviations from this recommendation may be indicated, since no average total daily dose can be defined but must be governed by close observation for clinical effects. OVERDOSAGE—Potassium intoxication may result from overdosage of potassium or from therapeutic dosage in conditions stated under "Contraindications." Hyperkalemia, when detected, must be treated immediately because lethal levels can be reached in a few hours. SUPPLIED: Pints and gallons. Dispense in amber glass containers.

When the symptoms add up to depression

ADAPIN®
(Doxepin HCl)

opens the patient to your counsel

Biphasic action helps you "get to" the depressed patient quickly.

Depressed patients are often difficult to reach. Some are lethargic; withdrawn. And in others, agitation masks the underlying depression.

Adapin (doxepin HCl) works on either—or both—phases: depression/agitation-depression. That's how Adapin quickly opens the patient to your counsel. Lets you work with him as the drug works to lift his depressive symptoms (usually in two to three weeks).

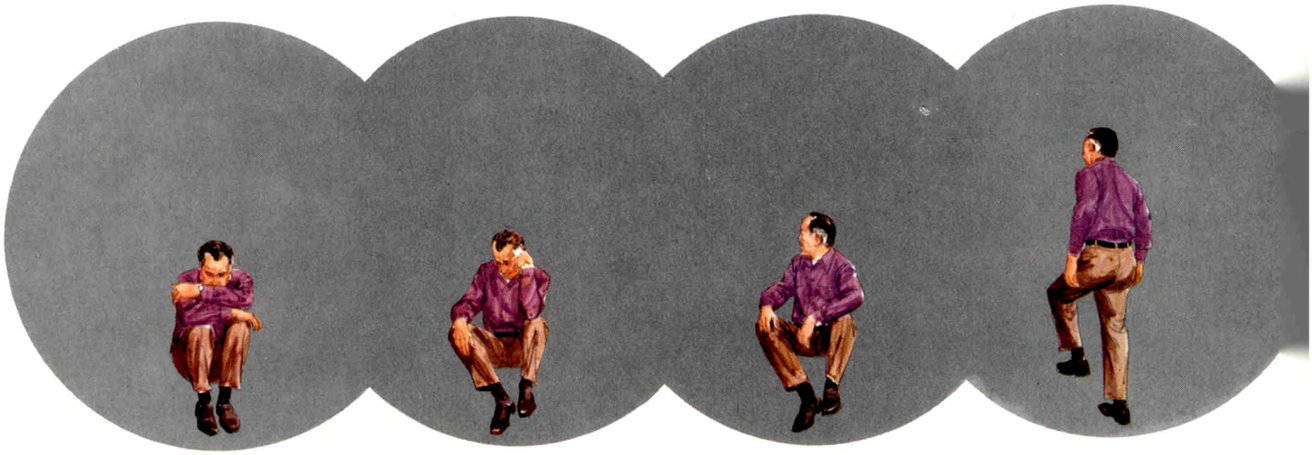
Dosage flexibility allows you to choose therapeutic approach.

In situations where drowsiness is clinically undesirable, you can start the patient on 10 mg. Adapin t.i.d. for four days (without reduced therapeutic effect) titrating the dosage upward after that as indicated. In patients where you deem drowsiness to be a desirable effect, you can initiate therapy with 25 mg. or more t.i.d. as the clinical situation dictates.

Further, with Adapin, you can titrate dosage upward in 10 mg. increments, allowing you greater therapeutic flexibility.

Single entity; low possibility of "cross reactions."

Adapin is single entity therapy. And there have been few reported instances of drug "cross reactions." In fact, one investigator[1] reported no adverse interactions between doxepin HCl [Adapin] and alcohol, hypnotics, neuroleptics, antihypertensive drugs, oral hypoglycemic agents, or anticonvulsants.



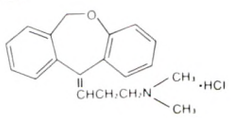
No addictive potential. No reported withdrawal symptoms.

Well tolerated by patients (even the elderly) with concomitant organic disease.

Low starting dosage; fine dosage titration.

1. Ayd, Frank J. Jr.: Long Term Administration of Doxepin. Dis Nerv Syst 32:617-22, Sept., 1971

Please see following page for prescribing information.



When the symptoms add up to depressio

ADAPIN®

(Doxepin HCl)

opens the patient to your counsel

COMPOSITION: Each Adapin capsule contains 10 mg., 25 mg., or 50 mg. of doxepin as the hydrochloride.

INDICATIONS: Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

CONTRAINDICATIONS: Adapin is contraindicated in patients with glaucoma or a tendency toward urinary retention, and in patients with demonstrated hypersensitivity to Adapin.

WARNINGS:

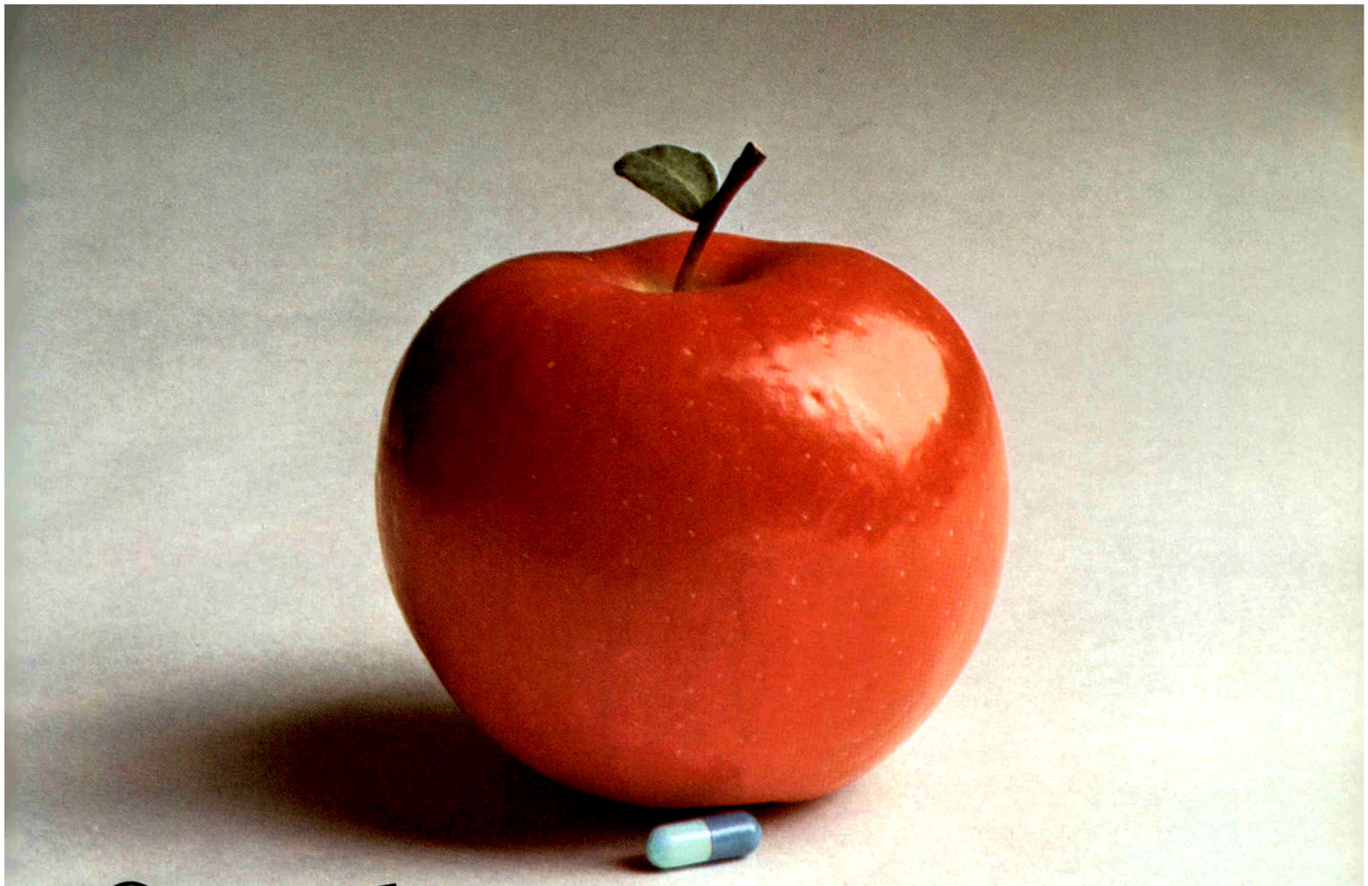
1. MAO inhibitors should be discontinued at least two weeks prior to cautious initiation of therapy with Adapin.
2. Adapin has not been evaluated in pregnant patients and should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.
3. Usage of Adapin in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Patients should be warned of the possible occurrence of drowsiness and cautioned against driving a motor vehicle or operating hazardous machinery. The effects of alcoholic beverages may be increased. Since suicide is an inherent risk in depressed patients, they should be closely supervised. The possibility of activating or unmasking latent psychotic symptoms during therapy should be kept in mind. Significant blocking of the antihypertensive effect of guanethidine is exerted at dosages of 300 mg. per day or higher. Potentiation of norepinephrine response in animals has been noted, but this effect has not been observed in humans.

ADVERSE REACTIONS: Anticholinergic Effects—Dry mouth, blurred vision and constipation; CNS Effects—Drowsiness; Cardiovascular Effects—Tachycardia and hypotension. Infrequently: extrapyramidal symptoms, gastrointestinal reactions, secretory effects (increased sweating), weakness, dizziness, fatigue, weight gains, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE: 10 mg. to 25 mg. t.i.d. to start. An initial dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients. Usual optimu dosage is 75 to 150 mg. per day. In some patients with mild emotional symptomatolog including that which may accompany organi disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control. More severe anxiety and/or depression may requi 50 mg. t.i.d. to start, gradually increased to 300 mg. per day.

OVERDOSAGE: Symptoms include an incre of the reported adverse reactions, primarily excessive sedation and anticholinergic effect as blurred vision and dry mouth. Other effect may be pronounced tachycardia, hypotensio and extrapyramidal symptoms. Treatment is essentially symptomatic with supportive therapy in the case of hypotension and excessive sedation.



SUPPLIED: Each capsule contains doxepin, the hydrochloride, 10 mg. (NDC 18-356-71) and 25 mg. (NDC 18-357-71) capsules in bottles of 100 and 50 mg. (NDC 18-358-65) capsules in bottles of 50. Caution: Federal law prohibits dispensing without a prescriptic

Once-a-day maintenance therapy. Introducing New Navane® 20 mg. (thiothixene) capsules

Once-a-day maintenance...

Once you've controlled acute psychosis or psychotic depression with a t.i.d. regimen, some patients can be maintained on one new Navane 20 mg. capsule a day. And for patients requiring higher dosages, two or three capsules, once a day, may be sufficient. This once-a-day regimen can reduce the risk of missed doses, with no loss of efficacy.

Once-a-day efficacy...

A recent double-blind, crossover study[1] compared Navane capsules, t.i.d., with an equivalent-dose once-a-day regimen. Both groups had statistically equivalent, significant clinical improvement over baseline at the end of the study period. And although the difference in extrapyramidal side effects was not statistically significant, the once-a-day group had a lower score.

Once-a-day economy...

For inpatient therapy, once-a-day Navane capsules can provide a saving of valuable nursing time. And for both institutions and outpatients, the 20-mg. capsule has another economy advantage: it's less costly than two 10-mg. or four 5-mg. capsules.

Navane 20-mg. It's a new dosage strength to maintain control of psychotic behavior. Effectively. Conveniently. And economically.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

1. Data on file, Roerig.

For prescribing information, including adverse reactions and contraindications, please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg., 2 mg., 5 mg., 10 mg., 20 mg.
Concentrate: 5 mg./cc.
Intramuscular: 2 mg./cc.

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg., 2 mg., 5 mg., 10 mg., 20 mg. (thiothixene hydrochloride).
Concentrate 5 mg./cc., Intramuscular 2 mg./cc.

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy* – Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane (thiothixene), there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg./kg./day), rabbits (3 to 50 mg./kg./day), and monkeys (1 to 3 mg./kg./day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane (thiothixene) may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane [thiothixene] for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis), have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration – As with all intramuscular preparations, Navane (thiothixene hydrochloride) Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the midlateral thigh.

The deltoid area should be used only if well developed such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower- and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following reactions have been reported with Navane. However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane (thiothixene) is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur, although it usually subsides with continuation of Navane therapy. The incidence of sedation appears to be similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: Although not reported with Navane, certain antipsychotic agents have been associated with persistent dyskinesias. Tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane (thiothixene) have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

NOTE: Sudden deaths have occasionally be reported in patients who have received cert phenothiazine derivatives. In some cases the cau of death was apparently cardiac arrest or asphy due to failure of the cough reflex. In others, t cause could not be determined nor could it established that death was due to phenothiazi administration because safe conditions for its u have not been established.

Dosage and Administration. Dosage of Nav should be individually adjusted depending on chronicity and severity of the condition. In ge eral, small doses should be used initially a gradually increased to the optimal effective lev based on patient response.

Usage in children under 12 years of age is n recommended.

Navane Intramuscular Solution—For Intram cular Use Only. Where more rapid control a treatment of behavior is desirable, the intram cular form of Navane (thiothixene hydrochlori may be indicated. It is also of benefit where very nature of the patient's symptomatolo whether acute or chronic, renders oral administ tion impractical or even impossible.

For treatment of acute symptomatology or patients unable or unwilling to take oral me cation, the usual dose is 4 mg. of Navane Int muscular administered 2 to 4 times daily. Dos may be increased or decreased depending on sponse. Most patients are controlled on a to daily dosage of 16 to 20 mg. The maximum r ommended dosage is 30 mg./day. An oral fo should supplant the injectable form as soon possible. It may be necessary to adjust the dos when changing from the intramuscular to o dosage forms. Dosage recommendations Navane Capsules and Concentrate appear in following paragraphs.

Navane Capsules: Navane Concentrate—milder conditions, an initial dose of 2 mg. th times daily. If indicated, a subsequent increase 15 mg./day total daily dose is often effective.

In more severe conditions, an initial dose 5 mg. twice daily.

The usual optimal dose is 20 to 30 mg. da If indicated, an increase to 60 mg./day total d dose is often effective. Exceeding a total d dose of 60 mg. rarely increases the beneficial sponse.

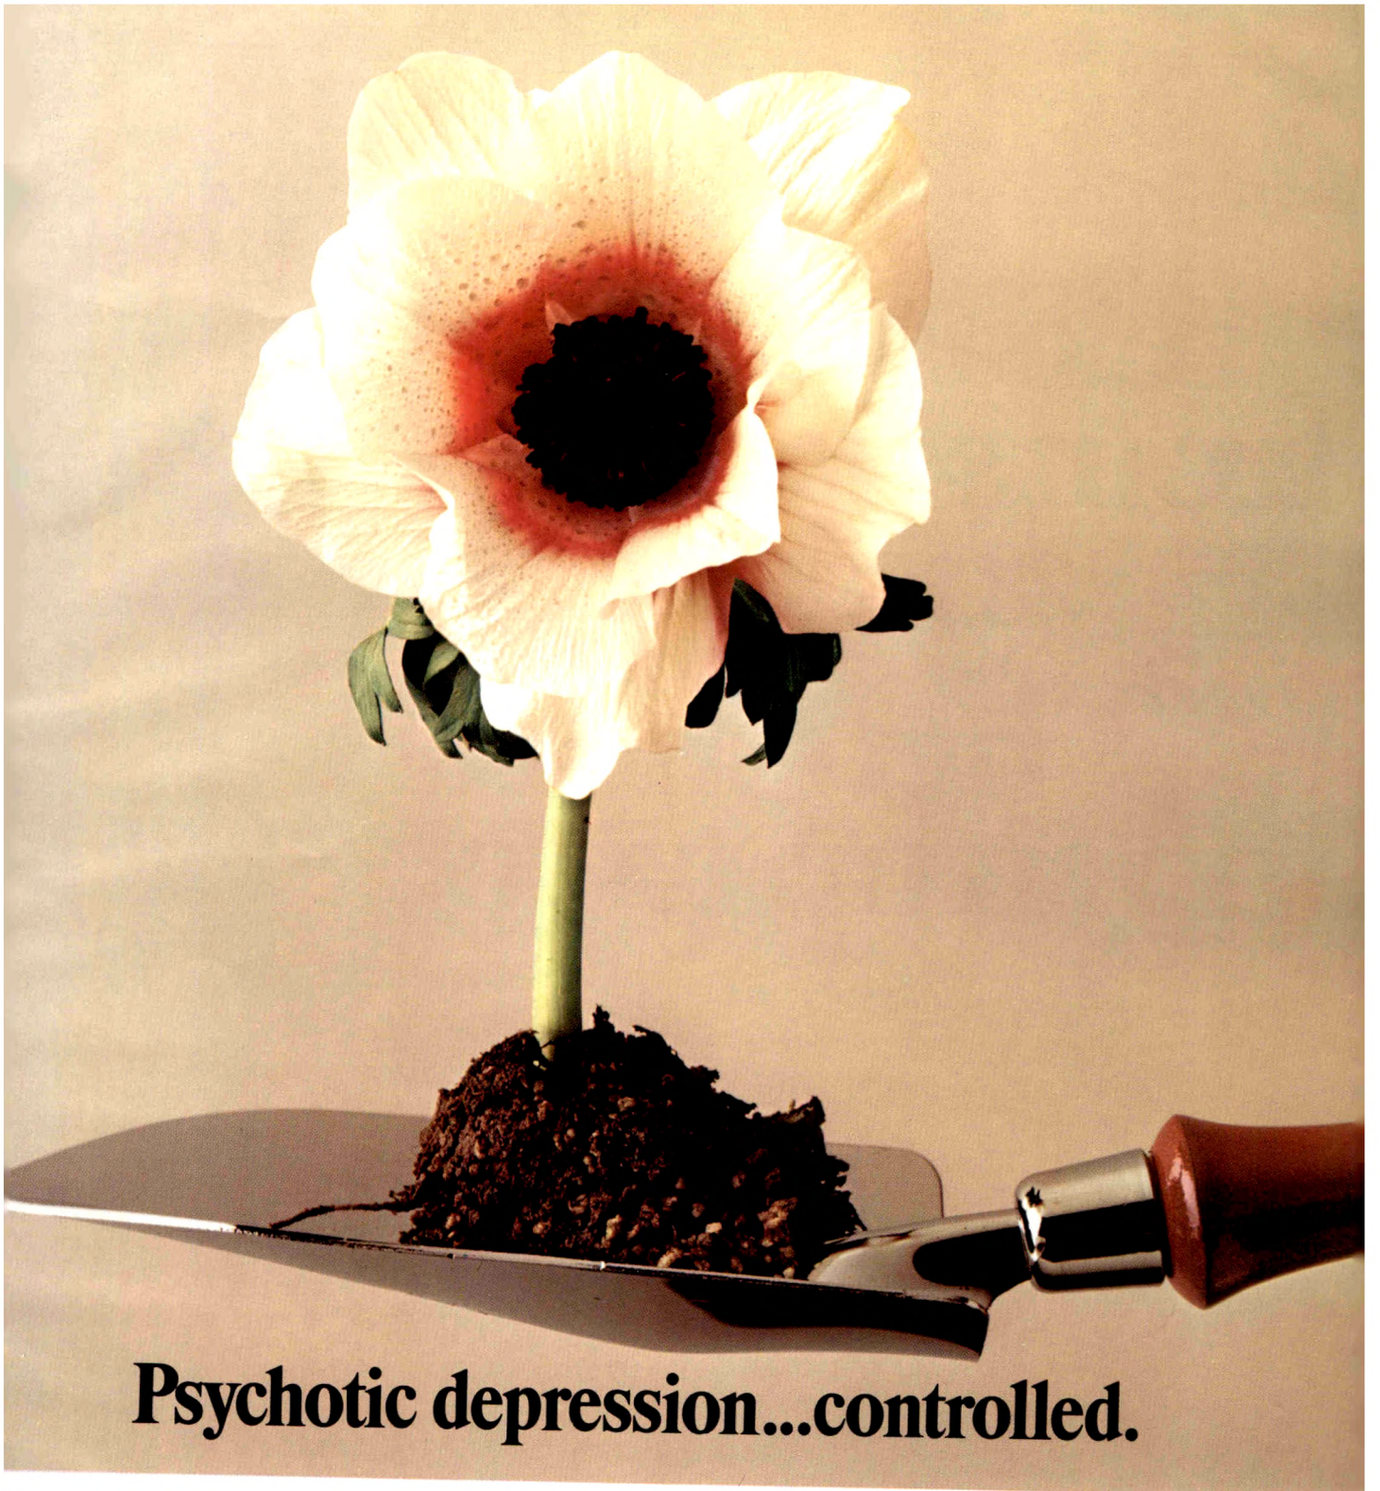
Some patients have been successfully maintain on once-a-day Navane (thiothixene) therapy.

Overdosage. Manifestations include muscu twitching, drowsiness, and dizziness. Symptoms gross overdosage may include CNS depressi rigidity, weakness, torticollis, tremor, salivati dysphagia, disturbances of gait, or coma.

Treatment: Essentially symptomatic and s portive. For Navane oral, early gastric lav is helpful. For Navane oral and intramuscu keep patient under careful observation and m tain an open airway, since involvement of extrapyramidal system may produce dysphag and respiratory difficulty in severe overdos If hypotension occurs, the standard measures managing circulatory shock should be used (I fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol phenylephrine are the most suitable drugs. Ot pressor agents, including epinephrine, are not r ommended, since phenothiazine derivatives m reverse the usual pressor action of these ag and cause further lowering of blood press

If CNS depression is present, recommen stimulants include amphetamine, dextroamph mine, or caffeine and sodium benzoate. Picroto or pentylenetetrazol should be avoided. Extra ramidal symptoms may be treated with antip kinson drugs.



There are no data on the use of peritoneal hemodialysis, but they are known to be of li value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is availa as capsules containing 1 mg., 2 mg., 5 mg., 10 mg. in bottles of 100 and 1,000. Navane is a available as capsules containing 20 mg. of th thixene, in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Conc trate is available in 120 cc. (4 oz.) bottles w an accompanying dropper calibrated at 2 mg mg., 5 mg., 6 mg., 8 mg. and 10 mg. Each contains thiothixene hydrochloride equivalent 5 mg. of thiothixene. Contains alcohol, U.S 7.0% v/v. (small loss unavoidable).

Navane (thiothixene hydrochloride) Intram cular Solution is available in a 2 cc. amber gl vial in packages of 10. Each cc. contains thioth ene hydrochloride equivalent to 2 mg. of thiothi ene, dextrose 5% w/v, benzyl alcohol 0.9% v

to help control psychotic depression

For prescribing information, including adverse reactions and contraindications, please see facing page of this advertisement.

Help release her from severe anxiety. Then she can open up to you.

Only with relief of the severe anxiety that often blocks verbalization can many patients expect to progress in therapy. To this end, Serax may prove beneficial, for it is now well established as an effective antianxiety adjunct. Serax offers flexibility as well. Dosage can be readily adjusted to individual needs. To the point where the patient may frequently resume normal work activities.

As with other CNS-acting drugs, patients should be cautioned against driving automobiles or operating dangerous machinery until it is known that they do not become drowsy or dizzy on oxazepam therapy. When prescribing, carefully observe dosage recommendations and appropriate precautions, especially as pertaining to the elderly or where a drop in blood pressure might lead to cardiac complications.

In severe anxiety

Serax®
(oxazepam)

Wyeth Laboratories
Philadelphia, Pa. 19101

Please see important information on page after next.

Help release her from severe anxiety.

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease.

Anxiety associated with depression is also responsive to oxazepam therapy.

This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients.

Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: *Use in Pregnancy:* Safety for use in pregnancy not established.

Precautions: Hypotensive reactions are rare, but use with caution where complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance.

Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

THE PURE GOLD OF OPINION...FROM DR. KARL MENNINGER

What does "Dr. Karl" think about when he's not working—or crusading? Everything in the world, including Kansas (he loves it), Freud, Schweitzer, "Deer Park" (he dislikes it), his parents, Kinsey, nature, politics, puzzles and earthworms. From his speeches, articles, *Reading Notes*, columns, letters and conversations, Lucy Freeman has created a full-fleshed portrait of the co-founder of the Menninger Clinic. And it is pure gold: irreverent, outspoken, sparkling.

R.S.V.P.

She just doesn't respond to things. No interest. No energy. Discouraged.

It may be mild depression. She needs help...and she needs it now.

Counsel and reassurance may suffice. But if you decide supportive medication is indicated, Ritalin can offer prompt benefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
(methylphenidate)
helps the patient respond in mild depression*

Ritalin® hydrochloride ©
(methylphenidate hydrochloride)

TABLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

CONTRAINDICATIONS
Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS
Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.
Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available.
Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.
Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.
Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.
Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.
Drug Interactions
Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported.
Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.

HEL ETI N HIS PERSPECTIVE ON REALITY

With effective management of psychotic symptoms

- Decreases delusions, auditory and visual hallucinations
- Lessens unusual thought content, paranoid ideation
- Allays underlying fear, anxiety and tension
- Controls hostility
- Calms hyperactive behavior
- Reduces emotional withdrawal

Before prescribing, see complete prescribing information including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

©1967, 1968, 1969 SmithKline Corporation

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

THORAZINE®

brand of

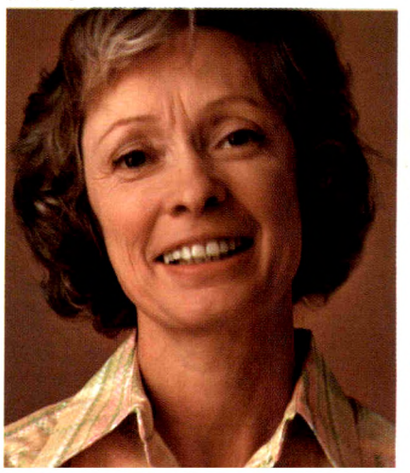
C L P OMAZI E

Tablets:
50 mg. of the HCl

· nervous · anxious
· irritable
· fatigued
· restless nights
While you're calming her down with a tranquilizer...

treat what may be her real problem with

PREMARIN® BRAND OF CONJUGATED ESTROGENS TABLETS, U.S.P.



She's come to you in a highly emotional state, with complaints of anxiety, nervousness, insomnia, and depression. And treatment with a psychotherapeutic agent may be appropriate for immediate relief of symptoms.

But considering her age, and her irregular menses, such symptoms may indicate an underlying estrogen deficiency... and the need for additional, more comprehensive therapy.

PREMARIN, by offering sound specific natural estrogen replacement, can provide such therapy ...relieve estrogen-related emotional symptoms of the menopause by treating their cause. Anxiety and depression related to estrogen deficiency usually respond to replacement therapy in a relatively short time.[1,2] Other "psychogenic" symptoms such as headaches, crying spells, insomnia, feelings of weakness and fatigue may also be relieved.[1,3-5]

And in a large majority of patients, PREMARIN imparts a renewed sense of well-being.[6] At the same time, PREMARIN helps control hot flushes, sweats, genital tissue atrophy, and, in selected cases, helps retard postmenopausal osteoporotic bone degeneration.*

When there is uncertainty as to the origin of emotional symptoms in the menopausal woman, a therapeutic trial with PREMARIN helps relieve those complaints that are estrogen-related...while helping to identify those that aren't.[7]

*Conjugated Estrogens Tablets have been evaluated as "probably" effective for postmenopausal osteoporosis.

when her real problem is estrogen deficiency

PREMARIN®
(CONJUGATED ESTROGENS TABLETS, U.S.P.)

contains only natural estrogens

for estrogen-related emotional symptoms

BRIEF SUMMARY
(For full prescribing information, see package circular.)

PREMARIN®
(Conjugated Estrogens Tablets, U.S.P.)

Indications: Based on a review of PREMARIN Tablets by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications for use as follows:
Effective: As replacement therapy for naturally occurring or surgically induced estrogen deficiency states associated with: the climacteric, including the menopausal syndrome and postmenopause; senile vaginitis and kraurosis vulvae, with or without pruritus.
"Probably" effective: For estrogen deficiency-induced osteoporosis, and only when used in conjunction with other important therapeutic measures such as diet, calcium, physiotherapy, and good general health-promoting measures. Final classification of this indication requires further investigation.

Contraindications: Short acting estrogens are contraindicated in patients with (1) markedly impaired liver function; (2) known or suspected carcinoma of the breast, except those cases of progressing disease not amenable to surgery or irradiation occurring in women who are at least 5 years postmenopausal; (3) known or suspected estrogen-dependent neoplasia, such as carcinoma of the endometrium; (4) thromboembolic disorders, thrombophlebitis, cerebral embolism, or in patients with a past history of these conditions; (5) undiagnosed abnormal genital bleeding.

Warnings: Estrogen therapy should not be given to women with recurrent chronic mastitis or abnormal mammograms except, if in the opinion of the physician, it is warranted despite the possibility of aggravation of the mastitis or stimulation of undiagnosed estrogen-dependent neoplasia.

The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, retinal thrombosis, cerebral embolism and pulmonary embolism). If these occur or are suspected, estrogen therapy should be discontinued immediately.

Estrogens may be excreted in the mother's milk and an estrogenic effect upon the infant has been described. The long range effect on the nursing infant cannot be determined at this time.

Hypercalcemia may occur in as many as 15 percent of breast cancer patients with metastases, and this usually indicates progression of bone metastases. This occurrence depends neither on dose nor on immobilization. In the presence of progression of the cancer or hypercalcemia, estrogen administration should be stopped.

A statistically significant association has been reported between maternal ingestion of diethylstilbestrol during pregnancy and the occurrence of vaginal carcinoma in the offspring. This occurred with the use of diethylstilbestrol for the treatment of threatened abortion or high risk pregnancies. Whether or not such an association is applicable to all estrogens is not known at this time. In view of this finding, however, the use of any estrogen in pregnancy is not recommended.

Failure to control abnormal uterine bleeding or unexpected recurrence is an indication for curettage.

Precautions: As with all short acting estrogens, the following precautions should be observed:

A complete pretreatment physical examination should be performed with special reference to pelvic and breast examinations.

To avoid prolonged stimulation of the endometrium and breasts in climacteric or hypogonadal women, estrogens should be administered cyclically (3 week regimen with 1 week rest period—withdrawal bleeding may occur during rest period).

Because of individual variation in endogenous estrogen production, relative overdosage may occur which could cause undesirable effects such as abnormal or excessive uterine bleeding, mastodynia and edema.

Because of salt and water retention associated with estrogenic anabolic activity, estrogens should be used with caution in patients with epilepsy, migraine, asthma, cardiac, or renal disease.

If unexplained or excessive vaginal bleeding should occur, reexamination should be made for organic pathology.

Pre-existing uterine fibromyomata may increase in size while using estrogens; therefore, patients should be examined at regular intervals while receiving estrogenic therapy.

The pathologist should be advised of estrogen therapy when relevant specimens are submitted.

Because of their effects on epiphyseal closure, estrogens should be used judiciously in young patients in whom bone growth is incomplete.

Prolonged high dosages of estrogens will inhibit anterior pituitary functions. This should be borne in mind when treating patients in whom fertility is desired.

The age of the patient constitutes no absolute limiting factor, although treatment with estrogens may mask the onset of the climacteric.

Certain liver and endocrine function tests may be affected by exogenous estrogen administration. If test results are abnormal in a patient taking estrogen, they should be repeated after estrogen has been withdrawn for one cycle.

Adverse Reactions: The following adverse reactions have been reported associated with short acting estrogen administration:
nausea, vomiting, anorexia
gastrointestinal symptoms such as abdominal cramps and bloating
breakthrough bleeding, spotting, unusually heavy withdrawal bleeding
(See DOSAGE AND ADMINISTRATION)
breast tenderness and enlargement
reactivation of endometriosis
possible diminution of lactation when given immediately postpartum
loss of libido and gynecomastia in males
edema
aggravation of migraine headaches
change in body weight (increase, decrease)
headache
allergic rash
hepatic cutaneous porphyria becoming manif

Dosage and Administration: PREMARIN sho be administered cyclically (3 weeks of daily est gen and 1 week off) for all indications e cept selected cases of carcinoma and preventi of postpartum breast engorgement.

Menopausal Syndrome—1.25 mg. daily, cy cally. Adjust dosage upward or downwa according to severity of symptoms and respor of the patient. For maintenance, adjust dosage lowest level that will provide effective control.

If the patient has not menstruated within t last two months or more, cyclic administratior started arbitrarily. If the patient is menstruatir cyclic administration is started on day 5 of blee ing. If breakthrough bleeding (bleeding or sp ting during estrogen therapy) occurs, increa estrogen dosage as needed to stop bleeding. the following cycle, employ the dosage level us to stop breakthrough bleeding in the previo cycle. In subsequent cycles, the estrogen dosa is gradually reduced to the lowest level which v maintain the patient symptom-free.

Postmenopause—as a protective measu against estrogen deficiency-induced degener tive changes (*e.g.* osteoporosis, atrophic va nitis, kraurosis vulvae)—0.3 mg. to 1.25 mg. da and cyclically. Adjust dosage to lowest effecti level.

Osteoporosis (to retard progression)—usu dosage 1.25 mg. daily and cyclically.

Senile Vaginitis, Kraurosis Vulvae with or wit out Pruritus—0.3 mg. to 1.25 mg. or more dai depending upon the tissue response of the in vidual patient. Administer cyclically.

How Supplied: PREMARIN (Conjugated Estr gens Tablets, U.S.P.) No. 865—Each *purple* tab contains 2.5 mg., in bottles of 100 and 1,00 No. 866—Each *yellow* tablet contains 1.25 m in bottles of 100 and 1,000. Also in unit dose pac age of 100. No. 867—Each *red* tablet contai 0.625 mg., in bottles of 100 and 1,000. No. 868 Each *green* tablet contains 0.3 mg., in bottles 100 and 1,000.

Clinical Notes on Group-Analytic Psychotherapy

By D. Wilfred Abse, *University of Virginia.* $6.50 (tnt.)

Group therapy is answering the need for psychiatric care for the large number of people in need of treatment—a number far exceeding that which qualified psychotherapists can handle on a one-to-one basis. This book meets the professional's need for an outline of the basic essentials for practicing group-analytic psychotherapy, and it offers criteria for determining when a patient would best benefit from such therapy. The author clearly defines group-analytic psychotherapy and outlines its history and present position in the field of mental health. He also suggests a method for determining the ideal group and the nature of the general pattern necessary for conducting group sessions. Dr. Abse builds a strong defense for group-analytic therapy, especially for the treatment of psychoneurotic patients who have serious difficulty with interpersonal relations.

Xenoglossy

By Ian Stevenson, *University of Virginia.* $8.50 (tnt.)

This is the first book written in English on xenoglossy—the ability of a person to speak a language other than his native one which he has not learned by any normal methods. Cases of xenoglossy are extremely rare. Even more rare are well-documented cases such as the major one presented in this volume. The book begins with an important and comprehensive review of all previously published instances of xenoglossy. The work then reports in detail a case of xenoglossy in which an American woman spoke Swedish. The hypnotized woman, here called T.E., underwent a transformation to a male personality which called itself Jensen and which spoke and understood Swedish in an intelligent way. The author follows with care the history of T.E., the background of Jensen, and concludes with good reasons to believe that the case cannot be fraudulent. Despite his support of its genuineness, he also discusses frankly alternative explanations for the case and other similar xenoglossy cases.

The Fear of Looking

or Scopophilic-exhibitionistic Conflicts

By David W. Allen, *University of California, San Francisco.* $7.95 (tnt.)

Scopophilia and exhibitionism have long been inadequately investigated even though a knowledge of them is crucial for understanding human behavior. This book brings scopophilia and exhibitionism out of obscurity and illustrates their importance in neuroses, in everyday life, and in treatment situations. It presents all the data and formulae available on scopophilia-exhibitionism and introduces the author's interpretations of its importance. Case histories are given which illustrate the importance of looking-showing influences in human behavior and demonstrate that scopophilic-exhibitionistic conflicts influence learning abilities, creativity, emotional distress, identity, and life styles. The book integrates information from such fields as neurophysiology, psychology, ethology, anthropology, and literature. It should interest not only psychiatrists and psychoanalysts but also sociologists, anthropologists, and artists. The author defines technical terms clearly so that the layman can easily read and understand the study.

Themes and Variations in European Psychiatry

An Anthology

Edited by Steven R. Hirsch, *Department of Psychiatry in Queen Mary's Hospital in Roehampton, England, and* Michael Shepherd, *University of London. Price to be announced.*

This volume of twenty-two papers by eighteen early influential explorers of psychiatry illustrates the breadth and depth of the mainstream of European psychiatric thinking. Only two of these papers have been printed before in English. This book will give English-speaking psychiatrists direct access to these important studies. The articles were chosen because they are still relevant to present-day psychiatric thinking, or because they represent a particularly characteristic concept or approach from another country which has no equal statement in English. The papers illustrate the approach of early clinical observers to issues that still pose major theoretical problems, such as the pathogenesis of psychiatric states including the role of psychogenesis; the distinction between pathoplastic and pathogenic factors and the status of the "reactive psychoses"; the limitations of clinical research; the phenomenology of individual syndromes and the distinction between them; the "paranoia" question; and several theoretical and conceptual frameworks that have been put forth by outstanding psychiatric thinkers.

Th TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication. And, of course, economy is an added factor in therapy with TRIAVIL.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

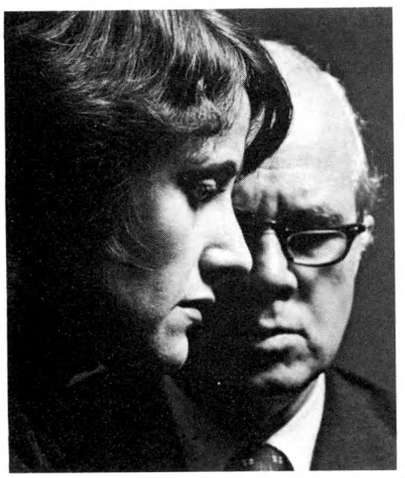
MERCK SHARP & DOHME



For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® (containing perphenazine and amitriptyline HCl)

an antidepressant tranquilizer

when patients exhibit moderate to marked anxiety
or agitation with symptoms of depression

TRIAVIL® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practic
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or ir testinal obstruction.
A significant, not otherwise explained, rise in body temperatur may suggest individual intolerance to perphenazine, in whic case discontinue.
If hypotension develops, epinephrine should not be employec as its action is blocked and partially reversed by perphenazine Phenothiazines may potentiate the action of central nervous sys tem depressants (opiates, analgesics, antihistamines, barbitu rates, alcohol) and atropine. In concurrent therapy with any c these, TRIAVIL should be given in reduced dosage. May als potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed pa tients may experience a shift toward the manic phase if the are treated with an antidepressant. Patients with paranoid symp tomatology may have an exaggeration of such symptoms. Th tranquilizing effect of TRIAVIL seems to reduce the likelihoo of this effect. When amitriptyline HCl is given with anticholir ergic agents or sympathomimetic drugs, including epinephrin combined with local anesthetics, close supervision and carefu adjustment of dosages are required.
Caution is advised if patients receive large doses of ethchlorvy nol concurrently. Transient delirium has been reported in pa tients who were treated with 1 g of ethchlorvynol and 75-15 mg of amitriptyline HCl.
Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy Such treatment should be limited to patients for whom it is essential.
Discontinue several days before elective surgery if possible Elevation and lowering of blood sugar levels have both beer reported.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyper-reflexia, dystonia, akathisia, dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine; skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and EKG abnormalities (quinidine-like effect); reactivation of psychotic

ocesses; catatonic-like states; autonomic reactions, such as yness of the mouth or salivation, headache, anorexia, nausea, miting, constipation, obstipation, urinary frequency or incon- nence, blurred vision, nasal congestion, and a change in pulse te; hypnotic effects; pigmentary retinopathy; corneal and nticular pigmentation; occasional lassitude; muscle weakness; lld insomnia. Other adverse reactions reported with various henothiazine compounds include blood dyscrasias (pancyto- enia, thrombocytopenic purpura, leukopenia, agranulocytosis, osinophilia); liver damage (jaundice, biliary stasis); grand mal onvulsions; cerebral edema; polyphagia; photophobia; skin gmentation; and failure of ejaculation.

nitriptyline: Note: Listing includes a few reactions not reported r this drug, but which have occurred with other pharmacologi- ally similar tricyclic antidepressant drugs. *Cardiovascular:* ypotension; hypertension; tachycardia; palpitation; myocardial farction; arrhythmias; heart block; stroke. *CNS and Neuro- uscular:* Confusional states; disturbed concentration; dis- rientation; delusions; hallucinations; excitement; anxiety; rest- ssness; insomnia; nightmares; numbness, tingling, and aresthesias of the extremities; peripheral neuropathy; incoordi- ation; ataxia; tremors; seizures; alteration in EEG patterns; xtrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; urred vision; disturbance of accommodation; constipation; aralytic ileus; urinary retention; dilatation of urinary tract. *llergic:* Skin rash; urticaria; photosensitivity; edema of face nd tongue. *Hematologic:* Bone marrow depression including granulocytosis; leukopenia; eosinophilia; purpura; thrombo- ytopenia. *Gastrointestinal:* Nausea, epigastic distress; vomiting; norexia; stomatitis; peculiar taste; diarrhea; parotid swelling; lack tongue. *Endocrine:* Testicular swelling and gynecomastia n the male; breast enlargement and galactorrhea in the female; ncreased or decreased libido; elevated or lowered blood sugar evels. *Other:* Dizziness; weakness; fatigue; headache; weight ain or loss; increased perspiration; urinary frequency; mydria- is; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt essation after prolonged administration may produce nausea, eadache, and malaise. These are not indicative of addiction.

VERDOSAGE: The intravenous administration of 1-3 mg of hysostigmine salicylate has been reported to reverse the ymptoms of amitriptyline poisoning. On this basis, in se- ere overdosage with perphenazine-amitriptyline combinations, ymptomatic treatment of central anticholinergic effects with hysostigmine salicylate should be considered.

For more detailed information, consult your MSD Representative or see full Prescribing nformation. Merck Sharp & Dohme, Division f Merck & Co., Inc., West Point, Pa. 19486.

MSD
MERCK SHARP & DOHME

MSD
MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance — vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration — in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

For the psychiatrist

The documented properties of DALMANE® (flurazepam HCl) for sleep

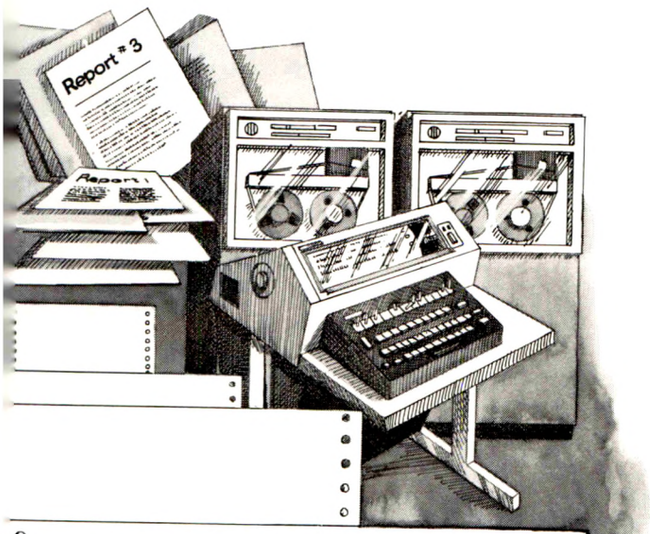
Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other available hypnotic.

The properties of Dalmane have been carefully defined and thoroughly evaluated. Results of these investigations—many of which are cited here—have documented the effectiveness and relative safety of Dalmane when the etiology of insomnia indicates need for sleep medication.

Prompt sleep induction, effective through the night[1-13]

Consistently effective night after night[2,3,5,6,8-13]

Relative safety[11,14,15*]



Usefulness in chronically anticoagulated patients[11]

Data about Dalmane (flurazepam HCl) on request

The references cited constitute only a part of the Dalmane bibliography. Additional data are available through the Roche Professional Services Department. Augmenting this service is RETRIEVE, a computer-operated data retrieval system which screens data from the published English language papers on Dalmane to help provide rapid answers to your specific questions. Coded into the computerized index are parameters that include patient age, sex, condition; product dose, side effect, frequency of administration; other medications or therapy; length, type and size of study, and pharmacology.

For specific answers to any questions you might have about Dalmane, write or call: Roche Professional Services Department, Roche Laboratories, Nutley, N.J. 07110. Telephone: (201) 235-2355.

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation, dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

DALMANE®
(flurazepam HCl)
When restful sleep is indicated

One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

CHILD PSYCHIATRY FELLOWSHIPS

New, Board Approved, Child Psychiatry Fellowships offered in an innovative, established clinical program. Outpatient, Community Child Psychiatry and Residential Treatment offer opportunities for a variety of treatment techniques. Crisis intervention ("life-space" interviews); behavioral therapy, pharmacotherapy; individual, group and family treatment methods; dynamic, social and developmental psychiatry taught. Learning by independent study, seminars, supervised experiences. Administrative experiences and training may be arranged. Multi-disciplinary staff including; six child psychiatrists, pediatrician, pediatric neurologist, psychologist, social workers, special education teachers, speech therapist, occupational therapists, recreational therapists and other consultants.

Program affiliated with the University of Michigan and a variety of clinical settings including; community mental health centers, child guidance clinics, etc. Salaries negotiable. Contact: William E. Kirk, M.D., Director, York Woods Center, Box A2, Ypsilanti, Michigan 48197. Phone: (313) 434-3400.

AN EQUAL OPPORTUNITY EMPLOYER

PSYCHIATRISTS

Hutchings Psychiatric Center has position available for well-trained, energetic Psychiatrists with clinical teaching and research interests. We are developing a new facility as a major part of a balanced system of service for five counties in Central New York. Our team Psychiatrist leads a 50-man multi-disciplinary team with inpatient, day care, and outpatient facilities. Hutchings Psychiatric Center is adjacent to Upstate Medical Center, and Syracuse University. Affiliated residents in psychiatry and family practice, as well as students in social work, rehabilitation, hospital administration, and psychiatric nursing provide teaching opportunities. A 14-man research staff is available for support of research interests.

Qualifications: Immediate openings are available for board eligible and board certified Psychiatrists. Salary range — $26,485 - $36,445 depending upon qualifications and experience.

Benefits: Vacation, Sick leave, personal leave, health insurance, dental insurance, New York State Retirement System, and major affiliation with S.U.N.Y. College of Medicine at Syracuse.

An Equal Opportunity Employer

1974 APA Appointment Books Desk and Pocket-sized

The "week-at-a-glance" Desk Appointment Book and the Pocket-sized version, published by the American Psychiatric Association, provide a quick and organized reference to your weekly engagements. As an added feature, it contains a comprehensive list of organizations and agencies of interest to psychiatrists and mental health professionals—in most cases director's name, address, phone number and date of forthcoming annual meeting are included. Also, there's a section to keep important phone numbers.

The Pocket-sized Appointment Book is 4" × 7 1/2", which is small enough to tuck inside your jacket, purse, suitcase or briefcase.

Desk: $5.00 ea.
Pocket: $3.00 ea.
Both: $7.00

Order 10 or more books for your colleagues or as gifts for your friends and take advantage of the 10% discount. Desk: $4.50 ea., Pocket-size: $2.70 ea. (15% discount for 100 or more copies)

Please send me
_____copy(ies) **Desk Appointment Book,** @$5.00 ea. order #141.

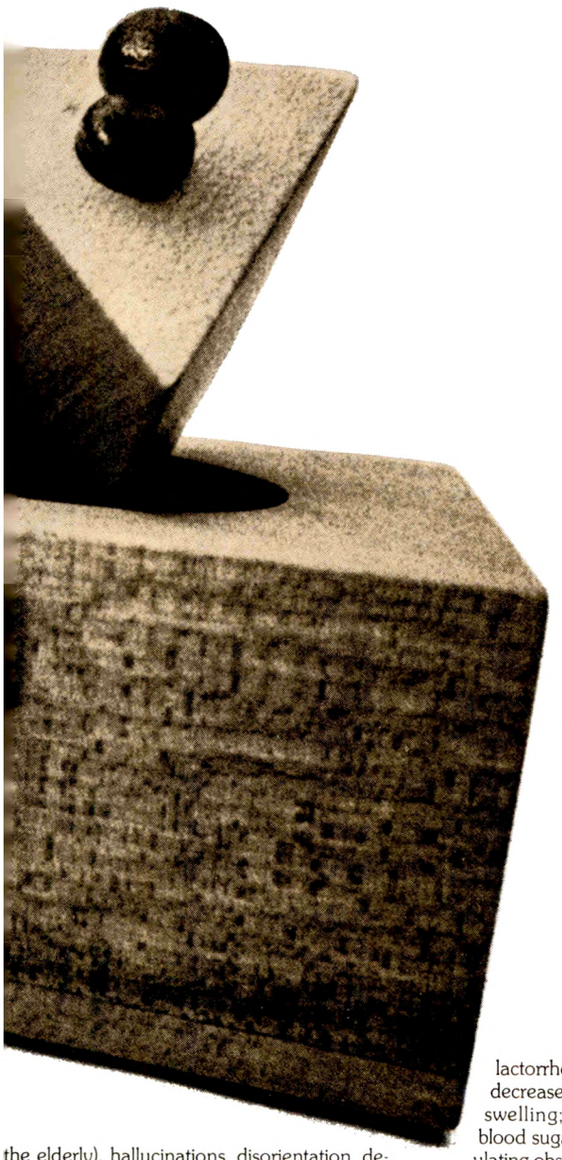
Help improve your depressed patients' ability to cope.

In Brief:

Actions: Norpramin® (desipramine hydrochloride) is an antidepressant drug of the tricyclic type. It has been found in some studies to have a more rapid onset of action than imipramine; antidepressant efficacy is similar though potency on a weight basis may be less. The earliest manifestations consist mainly of an increase in psychomotor activity. Full treatment benefit is seldom attained before the end of the second week.



Indications: Norpramin® (desipramine hydrochloride) is indicated for the relief of depressive symptoms. Endogenous depressions are more likely to be alleviated than others.

Contraindications: Desipramine hydrochloride should not be given within two weeks of treatment with a monoamine oxidase inhibitor. Contraindications include the acute recovery period following myocardial infarction and hypersensitivity to the drug. Cross sensitivity with other dibenzazepines is a possibility.

Warnings: 1. Extreme caution should be used in patients: (a) with cardiovascular disease, (b) with a history of urinary retention or glaucoma, (c) with thyroid disease or those on thyroid medication, (d) with a history of seizure disorder. 2. This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. 3. *Use in Pregnancy:* Safe use during pregnancy and lactation has not been established. 4. *Use in Children:* Norpramin® (desipramine hydrochloride) is not recommended for use in children. 5. This drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. Therefore, the patient should be cautioned accordingly.

Precautions: This drug should be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with drugs of this class. It should be kept out of reach of children. Reduce dosage, or alter treatment, if serious adverse effects occur. Norpramin® (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates and may cause exacerbation of psychos schizophrenic patients. Close supervision careful adjustment of dosage are required v this drug is given along with anticholinerg sympathomimetic drugs. While taking this c response to alcoholic beverages may be exa ated. There is limited clinical experience ir concurrent administration of ECT and an pressant drugs; thus, one should consider possibility of increased risk relative to ben Discontinue as soon as possible prior to ele surgery because of possible cardiovasc effects. Hypertensive episodes have b observed during surgery in patients on des mine hydrochloride. Leukocyte and differe counts should be performed in any patient develops fever and sore throat during the the drug should be discontinued if there is tropenia.

Adverse Reactions: *Cardiovascular:* hypo sion, hypertension, tachycardia, palpita arrhythmias, heart block, myocardial infarc stroke. *Psychiatric:* confusional states (espe

Coping with Depression

The ability to cope with depressive illness, for the patient and to some degree for the physician, largely depends on hope—a crutch that is usually lacking in the depressed patient. To the depressed patient all the good things of life are bleak, black, or unattainable; all that is bad has been happening or will happen. Helping such a patient to cope with life again, to overcome the incapacitating moods, outlooks, and fears which characterize depression, can be a most rewarding experience for the physician.

Although Norpramin® (desipramine hydrochloride) is relatively rapid-acting, the patient should be told that he will not feel better immediately but that he will gradually become his old self again. A minor tranquilizer in appropriate dosage may be used with Norpramin temporarily if anxiety due to depression is present; a phenothiazine may be used similarly if agitation is severe.

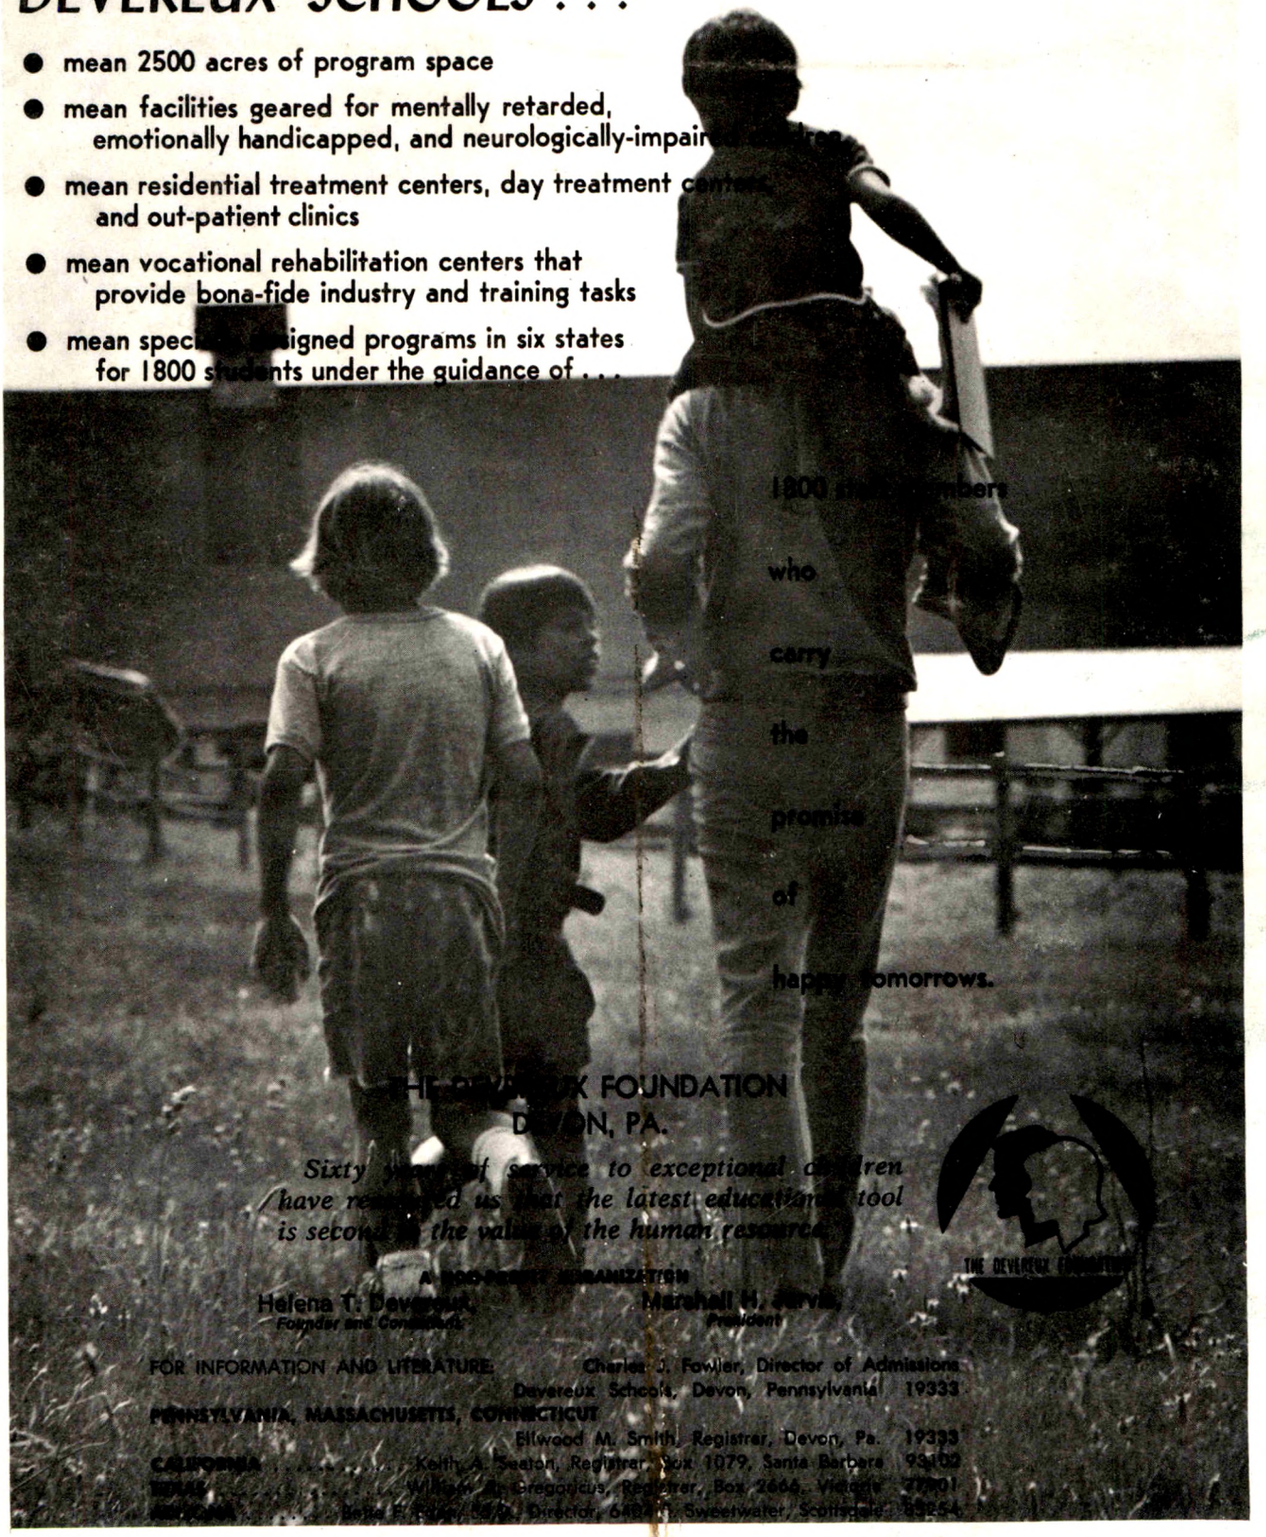
Frequently, Norpramin and your own understanding of the patient are all that is necessary.

Norpramin®
(desipramine hydrochloride)
helps the depressed cope with life again.

the elderly), hallucinations, disorientation, delusions; anxiety, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis. *Neurological:* paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus. *Anticholinergic:* dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, hypotonic bladder. *Allergic:* skin rash, petechiae, urticaria, itching, photosensitization, edema (of face and tongue or general), drug fever. *Hematologic:* agranulocytosis, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue. *Endocrine:* gynecomastia; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels. *Other:* jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia. *Withdrawal Symptoms:* Though not indicative of addiction, abrupt cessation after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: *The usual adult dose:* 50 mg. three times daily; increase if necessary after 7 to 10 days to maximum of 200 mg. daily. Dosages above 200 mg. per day are not recommended. *Maintenance:* At a lower dose adequate to maintain remission. *Adolescent and geriatric patient dose:* 25 to 50 mg. daily if necessary.

Overdosage: There is no specific antidote for desipramine, nor are there specific phenomena of diagnostic value characterizing poisoning by the drug. The principles of management of coma and shock by means of the mechanical respirator, cardiac pacemaker, monitoring of central venous pressure and regulation of fluid- and acid-base balance are well known in most medical centers. If heart failure is imminent, digitalize promptly.



How Supplied: Norpramin® (desipramine hydrochloride) *25 mg.*, sugar coated tablets, yellow, in bottles of 50, 500 and 1000 tablets. Norpramin® (desipramine hydrochloride) *50 mg.*, sugar coated tablets, light green, in bottles of 50, 250 and 1000 tablets.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the Editor or Managing Editor.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal*'s Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interaction between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, The Psychiatric Consultation. Edited by Mendel W, Solomon H. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHOR'S CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

Today, she managed a smile

(Not long ago, she couldn't stop sobbing)

Before he sees that first positive response—however hesitant and tentative—the physician may have to bring into play many different aspects of therapy. Establishing a therapeutic relationship may be the first difficulty as well as the first necessity. Psychotherapy, family and community support, occupational and social counseling, and drug therapy may all have to be enlisted.

The characteristically rapid energizing action of VIVACTIL may help establish early therapeutic rapport by lessening the patient's lethargy—often during the first week of medication. VIVACTIL helps elevate mood, usually within the third or fourth week of treatment.

Characteristically, the drug has no sedating or tranquilizing properties. (Symptoms such as anxiety or agitation may be aggravated.)

Dosage of VIVACTIL must be individualized and patients should be under close medical supervision. For many adult patients with clinically significant depression, 10 mg t.i.d. may provide control of symptoms. Others may require as little as 15 mg or as much as 60 mg a day. In elderly patients and adolescents, lower dosages are recommended.

In depression,

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD)

helps establish early therapeutic rapport

ontraindications: Known hypersensitivity; acute recovery phase following myocardial farction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe nvulsions, and deaths have occurred in patients receiving tricyclic antidepressant and AOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, minimum of 14 days should be allowed to elapse after the latter is discontinued. Protiptyline HCl should then be initiated cautiously with gradual increase in dosage until ptimum response is achieved.

arnings: May block the antihypertensive effect of guanethidine or similarly acting compunds. May impair mental and/or physical abilities required for the performance of hazardus tasks, such as operating machinery or driving a motor vehicle. Should be used with ution in patients with a history of seizures and, because of its autonomic activity, in tients with a tendency to urinary retention or increased intraocular tension.

achycardia and postural hypotension may occur more frequently than with other antipressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of e drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conuction time. Myocardial infarction and stroke have occurred with drugs of this class. n rare occasions, hyperthyroid patients or those receiving thyroid medication ay develop arrhythmias when this drug is given.

ge in Children: Not recommended for use in children because safety and effectiveness the pediatric age group have not been established.

ge in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, e in pregnant women, nursing mothers, or women who may become pregnant requires at possible benefits be weighed against possible hazards to mother and child.

ecautions: When protriptyline HCl is used to treat the depressive component of schizorenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, pressed patients may experience a shift toward the manic phase; paranoid delusions, th or without associated hostility, may be exaggerated. In any of these circumstances, it ay be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug ncurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive agitated patients.

hen given with anticholinergic agents or sympathomimetic drugs, including epinephrine mbined with local anesthetics, close supervision and careful adjustment of dosages are quired. May enhance response to alcohol and effects of barbiturates and other CNS pressants. Possibility of suicide in depressed patients remains during treatment and til significant remission occurs; this type of patient should not have easy access to rge quantities of the drug. Concurrent administration with electroshock therapy may crease hazards of therapy; such treatment should be limited to patients for whom it is ssential. Discontinue drug several days before elective surgery, if possible. Both elevation d lowering of blood sugar levels have been reported.

dverse Reactions: *Note:* Included in this listing are a few adverse reactions which have t been reported with this specific drug. However, the pharmacologic similarities among e tricyclic antidepressant drugs require that each of the reactions be considered when otriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation d anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

rdiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, rhythmias, heart block, stroke.

ychiatric: confusional states (especially in the elderly) with hallucinations, disorientaon, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightares; hypomania; exacerbation of psychosis.

eurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, emors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG atterns, tinnitus.

ntricholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed icturition, dilatation of the urinary tract.

llergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exosure to sunlight), edema (general, or of face and tongue), drug fever.

ematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; rombocytopenia.

astrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, tomatitis, abdominal cramps, black tongue.

ndocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; ncreased or decreased libido, impotence; testicular swelling; elevation or depression of lood sugar levels.

ther: jaundice (simulating obstructive); altered liver function; weight gain or loss; erspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and tigue; headache; parotid swelling; alopecia.

ithdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after rolonged therapy may produce nausea, headache, and malaise.

verdosage: The intravenous administration of 1 to 3 mg physostigmine salicylate has been eported to reverse the symptoms of amitriptyline poisoning in humans. Animal studies ave shown that physostigmine also reverses certain toxic effects of protriptyline, but to lesser extent.

low Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit ackages of 100 and bottles of 100 and 1000.

or more detailed information, consult your MSD representative or see full prescribing information.
Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

addendum

MSD
MERCK SHARP & DOHME

MSD 88 5 mg (orange)

MSD 47 10 mg (yellow)

The usual regimen for adults is 15 to 40 mg a day divided into three or four doses. Dosage may be increased to 60 mg a day if necessary.

In elderly and adolescent patients, lower dosages are recommended; initially, a regimen of 5 mg t.i.d. is suggested with adjustment as necessary to the required amount. In elderly patients, the cardiovascular system must be monitored closely when the daily dose exceeds 20 mg.

Because VIVACTIL (Protriptyline HCl, MSD) characteristically is a nonsedating tricyclic antidepressant, activating and energizing in effect, the last dose of the day should be given no later than mid-afternoon to avoid insomnia. Required increases should be added to the morning dose.

When necessary to increase dosage, it should be done gradually. After satisfactory improvement has been achieved, dosage should be reduced to the smallest amount that will maintain relief of symptoms. Maintenance therapy should be continued for at least three months after satisfactory improvement occurs.

(*Usage in Children:* In view of the lack of experience in children, this drug is not recommended for patients under 12 years of age.)

The Country Place

LITCHFIELD, CONNECTICUT

THE COUNTRY PLACE is a residential community for the emotionally disturbed adult who has more insight than he can use, who knows how he should act but withdraws from action.

THE COUNTRY PLACE offers
a home where he is understood
a work place where he can cope with the demands
a community where he can find social identity

THE COUNTRY PLACE
provides team work in socially useful projects
self help through interaction in groups
exploration of existent reality

THE COUNTRY PLACE maintains a well-trained professional staff for individual and group therapy psychodrama, art, dance and music therapy, as well as sports and games

WEEK END WORKSHOPS for professionals interested in studying our method of helping the disturbed person in creating a new identity

An Overview on

Trends in Psychiatric Research

by H. Keith H. Brodie

and Melvin Sabshin

We've got a new name

A (potassium gluconate-potassium chloride)

(but that's all).

KALYUM™ Liquid (potassium gluconate-potassium chloride), that's our old name. The name you knew us by.

We liked it. After all it's the Latin pronunciation for "potassium." And potassium supplementation is what we're all about.

So why change our name to KOLYUM™ Liquid (potassium gluconate-potassium chloride)?

It just happens that our old name could possibly be mistaken for the name of a large product in another therapeutic category. So we decided to eliminate any chance of confusion by changing *our* name.

But our name is all we changed. Kolyum (new name) is still the same good-tasting cherry flavored potassium supplement you trusted under the name of Kalyum.

So from now on—whenever you want effective potassium supplementation *without sodium and calories*, remember our new name: Kolyum Liquid.

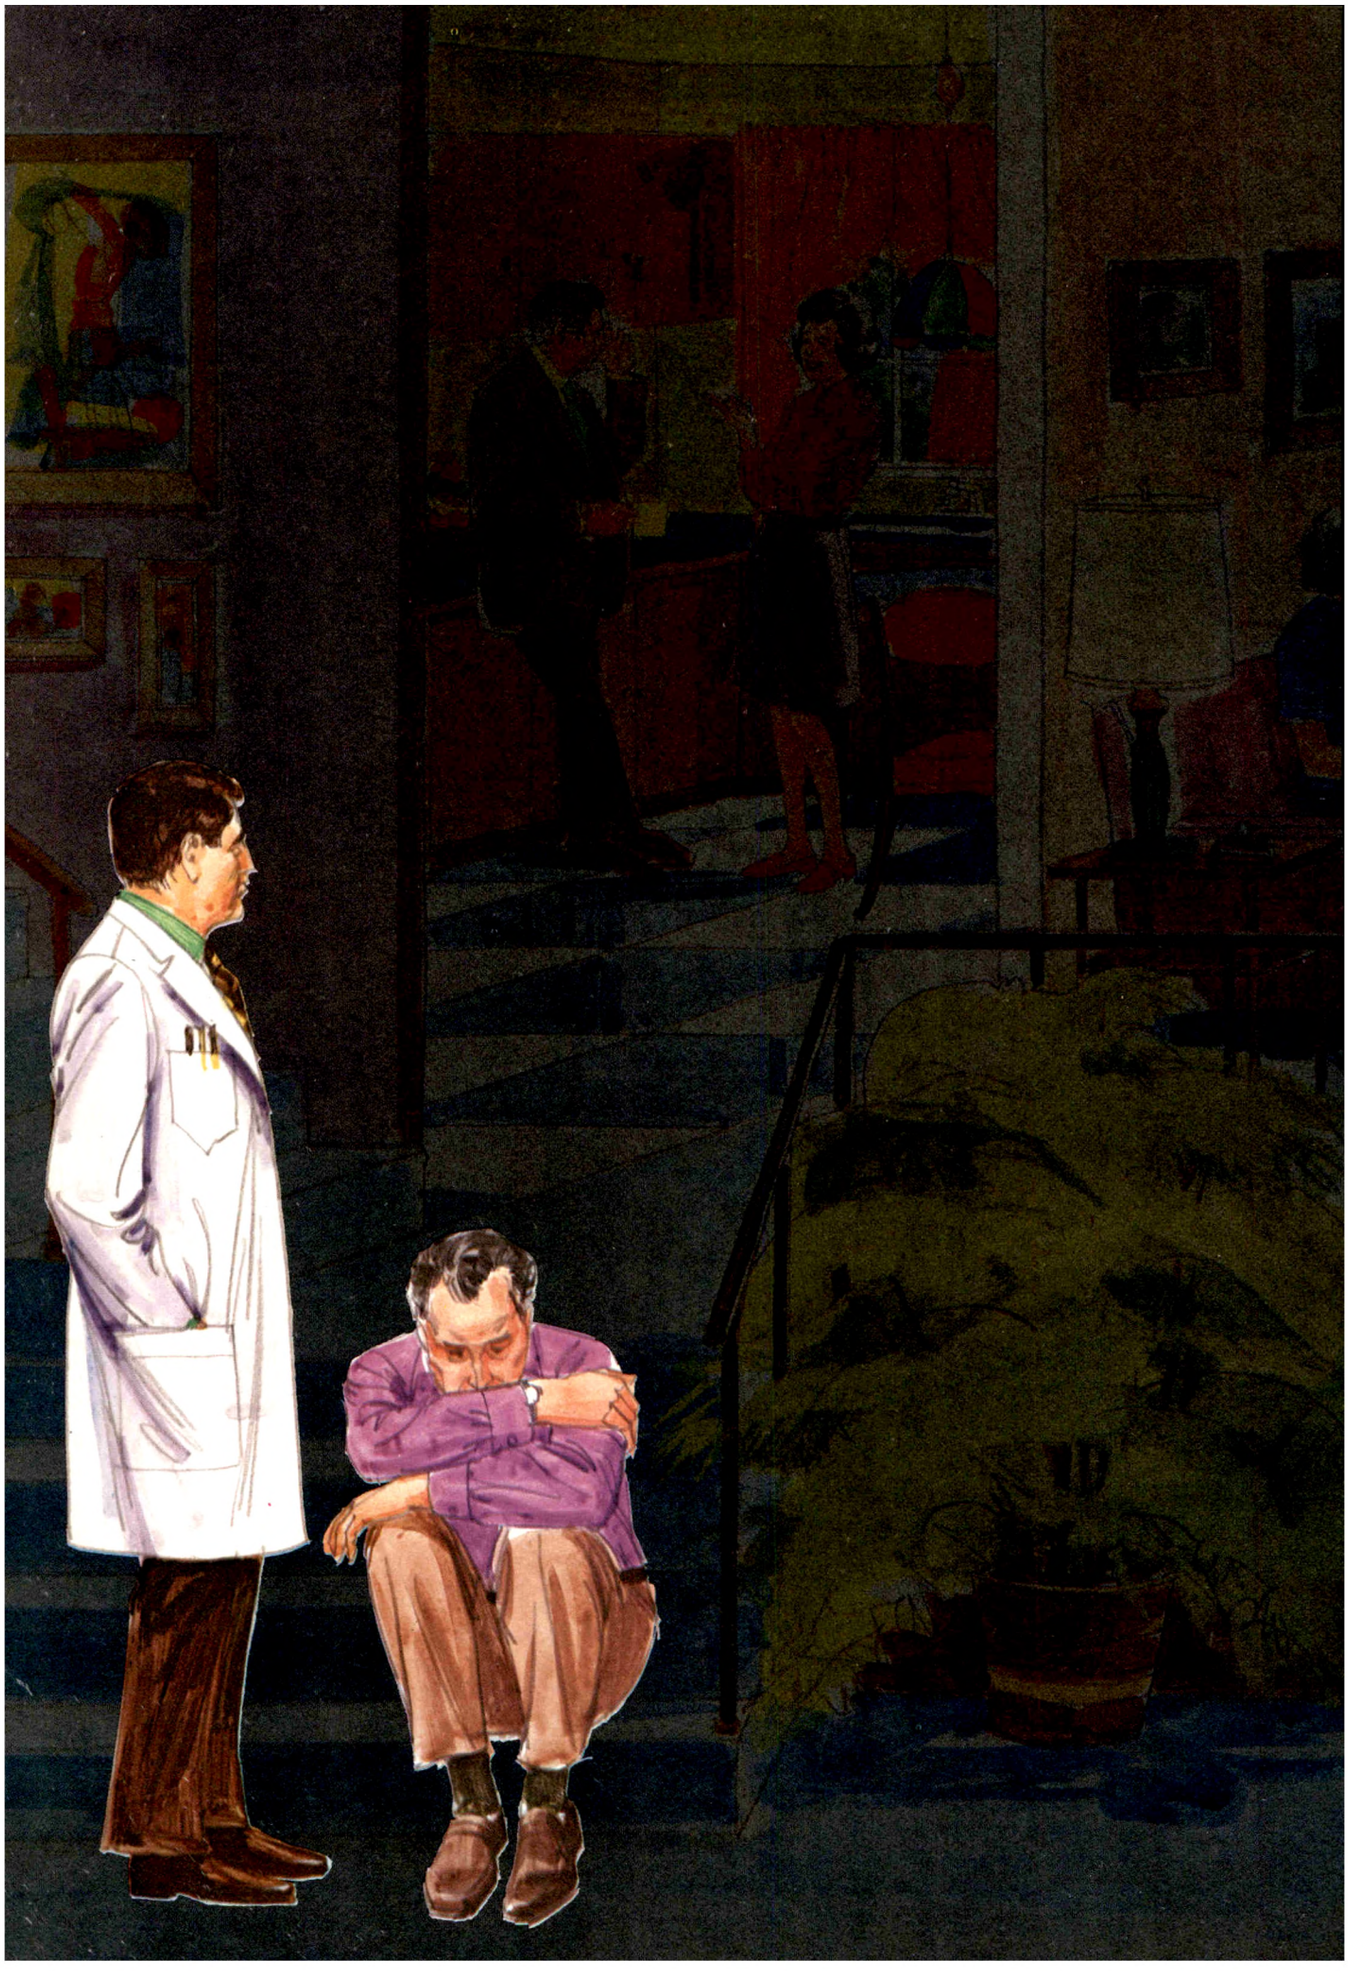
Kolyum Liquid.

Potassium supplementation gets a neat new name.

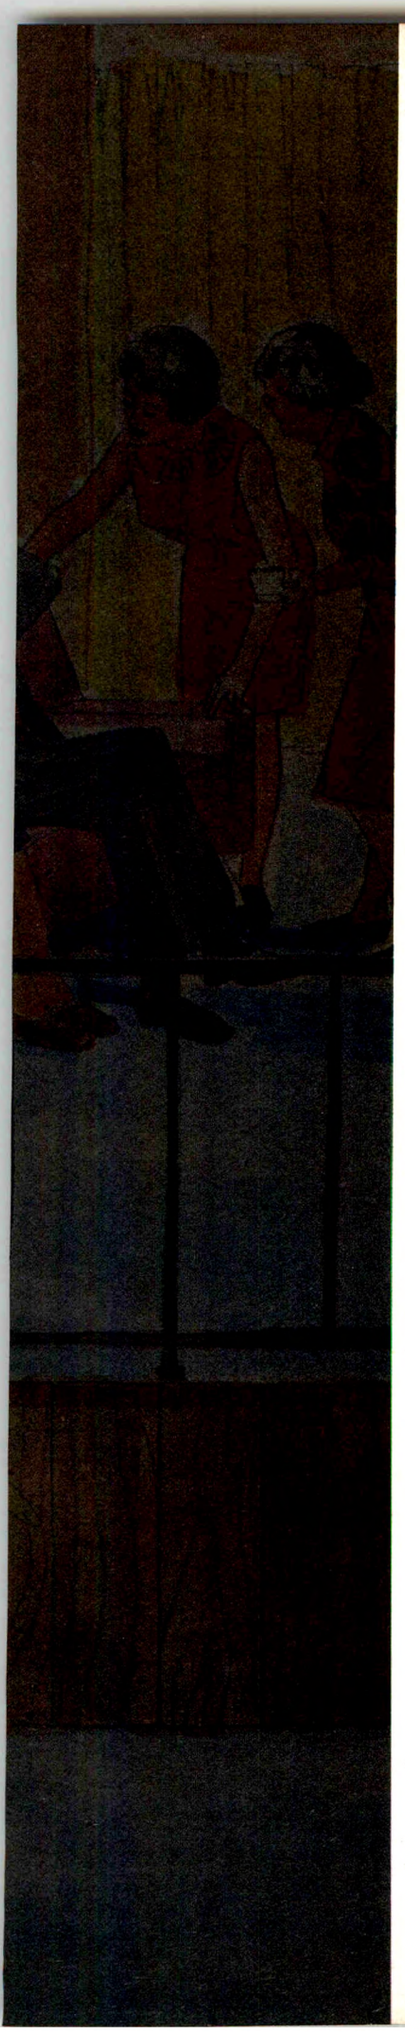
PRESCRIBING INFORMATION

DESCRIPTION—Each 15 ml tablespoon provides 20 mEq. of potassium ion and 3.34 mEq. of chloride ion in a sugar free, cherry flavored vehicle.

INDICATION—Oral potassium therapy for the prevention and treatment of hypokalemia which may occur secondary to diuretic or corticosteroid administration. May be used in the treatment of cardiac arrhythmias due to digitalis intoxication.



CONTRAINDICATIONS—Severe renal impairment with oliguria or azotemia, untreated Addison's disease, adynamia episodica hereditaria, acute dehydration, heat cramps and hyperkalemia from any cause.



PRECAUTIONS—Potassium supplements must be administered with caution, since the amount of the deficiency or daily dosage is not accurately known. Frequent checks of the clinical status of the patient, and periodic ECG and/or serum potassium levels should be made. High serum concentrations of potassium ion may cause death through cardiac depression, arrhythmias or arrest. This drug should be used with caution in the presence of cardiac disease. Extreme caution should be used in patients receiving aldosterone antagonists or potassium sparing diuretics. In both cases potassium intoxication might occur.

ADVERSE REACTIONS—Nausea, vomiting, diarrhea and abdominal discomfort have been reported. The symptoms and signs of potassium intoxication include paresthesias of the extremities, flaccid paralysis, listlessness, mental confusion, weakness and heaviness of the legs, fall in blood pressure, cardiac arrhythmias and heart block. Hyperkalemia may exhibit the following electrocardiographic abnormalities: disappearance of the P wave, widening and slurring of QRS complex, changes of the S-T segment and tall peaked T waves. DOSAGE—The usual adult dosage is one tablespoonful (15 ml.) in one fluid ounce or more of water twice daily. This supplies 40 mEq. of potassium ion which is the approximate minimal adult daily requirement, as well as 6.68 mEq. of chloride ion. Deviations from this recommendation may be indicated, since no average total daily dose can be defined but must be governed by close observation for clinical effects. OVERDOSAGE—Potassium intoxication may result from overdosage of potassium or from therapeutic dosage in conditions stated under "Contraindications." Hyperkalemia, when detected, must be treated immediately because lethal levels can be reached in a few hours. SUPPLIED: Pints and gallons. Dispense in amber glass containers.

When the symptoms add up to depression

ADAPIN®
(Doxepin HCl)

opens the patient to your counsel

Biphasic action helps you "get to" the depressed patient quickly.

Depressed patients are often difficult to reach. Some are lethargic: withdrawn. And in others, agitation masks the underlying depression.

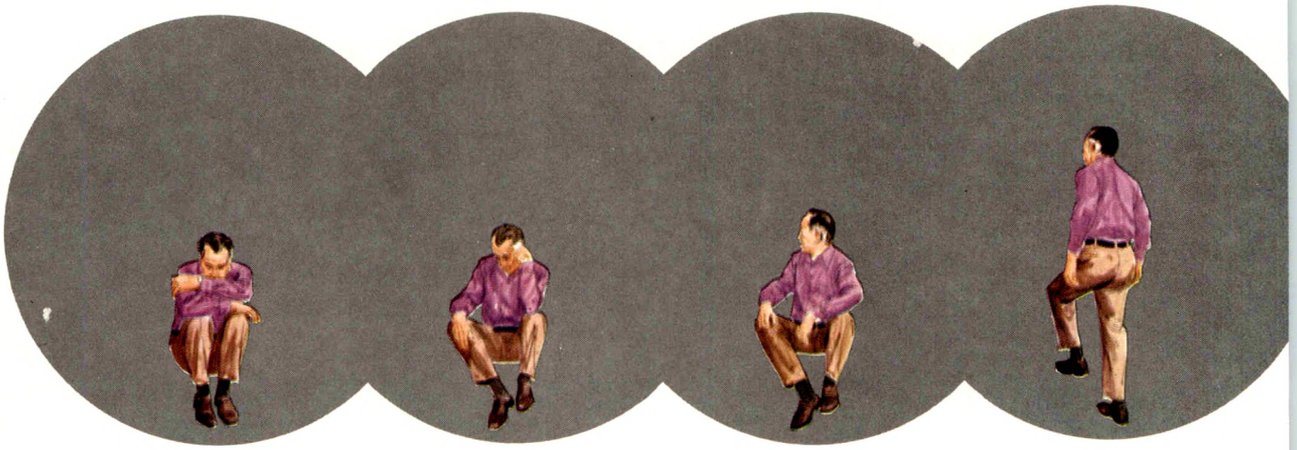
Adapin (doxepin HCl) works on either—or both—phases: depression/agitation-depression. That's how Adapin quickly opens the patient to your counsel. Lets you work with him as the drug works to lift his depressive symptoms (usually in two to three weeks).

Dosage flexibility allows you to choose therapeutic approach.

In situations where drowsiness is clinically undesirable, you can start the patient on 10 mg. Adapin t.i.d. for four days (without reduced therapeutic effect) titrating the dosage upward after that as indicated. In patients where you deem drowsiness to be a desirable effect, you can initiate therapy with 25 mg. or more t.i.d. as the clinical situation dictates.

Further, with Adapin, you can titrate dosage upward in 10 mg. increments, allowing you greater therapeutic flexibility.

Single entity; low possibility of "cross reactions."



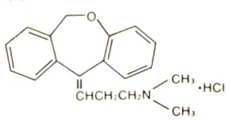
Adapin is single entity therapy. And there have been few reported instances of drug "cross reactions." In fact, one investigator reported no adverse interactions between doxepin HCl and alcohol, hypnotics, neuroleptics, antihypertensive drugs, oral hypoglycemic agents, or anticonvulsants.

No addictive potential. No reported withdrawal symptoms.

Well tolerated by patients (even the elderly) with concomitant organic disease.

Low starting dosage; fine dosage titration.

Please see following page for prescribing information.



When the symptoms add up to depressio

ADAPIN®

(Doxepin HCl)

opens the patient to your counsel

COMPOSITION: Each Adapin capsule contains 10 mg., 25 mg., or 50 mg. of doxepin as the hydrochloride.

INDICATIONS: Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

CONTRAINDICATIONS: Adapin is contraindicated in patients with glaucoma or a tendency toward urinary retention, and in patients with demonstrated hypersensitivity to Adapin.

WARNINGS:

1. MAO inhibitors should be discontinued at least two weeks prior to cautious initiation of therapy with Adapin.
2. Adapin has not been evaluated in pregnant patients and should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.
3. Usage of Adapin in children under 12 years of age is not recommended because safe conditions for its use have not been established.

PRECAUTIONS: Patients should be warned of the possible occurrence of drowsiness and cautioned against driving a motor vehicle or operating hazardous machinery. The effects of alcoholic beverages may be increased. Since suicide is an inherent risk in depressed patients, they should be closely supervised. The possibility of activating or unmasking latent psychotic symptoms during therapy should be kept in mind. Significant blocking of the antihypertensive effect of guanethidine is exerted at dosages of 300 mg. per day or higher. Potentiation of norepinephrine response in animals has been noted, but this effect has not been observed in humans.

ADVERSE REACTIONS: Anticholinergic Effects—Dry mouth, blurred vision and constipation; CNS Effects—Drowsiness; Cardiovascular Effects—Tachycardia and hypotension. Infrequently: extrapyramidal symptoms, gastrointestinal reactions, secretory effects (increased sweating), weakness, dizziness, fatigue, weight gains, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE: 10 mg. to 25 mg. t.i.d. to start. An initial dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients. Usual optimum dosage is 75 to 150 mg. per day. In some patients with mild emotional symptomatology, including that which may accompany organic disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control. More severe anxiety and/or depression may require 50 mg. t.i.d. to start, gradually increased to 300 mg. per day.

OVERDOSAGE: Symptoms include an increase of the reported adverse reactions, primarily excessive sedation and anticholinergic effects such as blurred vision and dry mouth. Other effects may be pronounced tachycardia, hypotension and extrapyramidal symptoms. Treatment is essentially symptomatic with supportive therapy in the case of hypotension and excessive sedation.

SUPPLIED: Each capsule contains doxepin, as the hydrochloride, 10 mg. (NDC 18-356-71) and 25 mg. (NDC 18-357-71) capsules in bottles of 100 and 50 mg. (NDC 18-358-65) capsules in bottles of 50. Caution: Federal law prohibits dispensing without a prescription.

recovery room

The psychiatric setting... and the role of TRIAVIL®.

Change, growth, and insight can flourish in this private and protected place, for seldom is the doctor-patient relationship more meaningful than in this psychotherapeutic setting. There are situations and stages, however, when time and talk are not enough... when the careful use of a psychotropic agent such as TRIAVIL can help accelerate recovery. Specifically, when TRIAVIL is part of the treatment program, you may anticipate these important therapeutic benefits:

The TRIAVIL Potential

1. By relieving moderate to severe anxiety or agitation with depression, the patient may become more accessible and cooperative.
2. As somatic manifestations of anxiety and depression are controlled, attention may be focused on the underlying factors of the condition.
3. While the psychotherapeutic process proceeds, symptomatic relief may enable the patient to function more effectively in his daily activities.

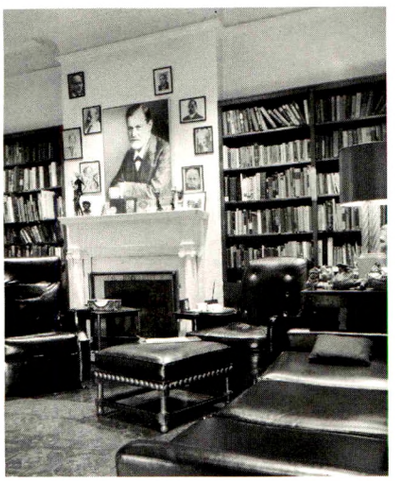
In addition, since TRIAVIL combines a tranquilizer with an antidepressant, confused and troubled patients need remember to take only one type of tablet, rather than two. And patients are offered economical therapy compared to a tranquilizer and an antidepressant prescribed separately.

Treatment with TRIAVIL a balanced view.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Close supervision of patients is essential, particularly until satisfactory remission has taken place. Suicide is inherent in any depressive illness so patients should not have easy access to large quantities of the drug. The drug may impair alertness and potentiate the response to alcohol. It should not be used during the acute recovery phase following myocardial infarction or given to patients who have received an MAOI within two weeks. TRIAVIL should be used with caution in glaucoma and in patients prone to urinary retention. It is contraindicated in CNS depression and in the presence of evidence of bone marrow depression.

a tranquilizer – antidepressant

Triavil®



a potential aid in the psychotherapeutic process when patients exhibit moderate to marked anxiety or agitation with depression

containing perphenazine and amitriptyline HCl

MSD
MERCK SHARP & DOHME

For additional prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety
or agitation with depression

Triavil® 4-25

Each tablet contains
4 mg. perphenazine and
25 mg. amitriptyline HCl

a formulation particularly suited to psychiatric practice
when higher doses are required.

Also Available:
TRIAVIL® 2-25: Each tablet contains
2 mg. perphenazine and 25 mg. amitriptyline HCl.

TRIAVIL® 2-10: Each tablet contains
2 mg. perphenazine and 10 mg. amitriptyline HCl.

TRIAVIL® 4-10: Each tablet contains
4 mg. perphenazine and 10 mg. amitriptyline HCl.

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, narcotics, analgesics, antihistamines) and alcohol; bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased ocular pressure, or convulsive disorders. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.
Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction.
A significant, not otherwise explained, rise in body temperatur may suggest individual intolerance to perphenazine, in whic case discontinue.
If hypotension develops, epinephrine should not be employed as its action is blocked and partially reversed by perphenazine
Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any o these, TRIAVIL should be given in reduced dosage. May als potentiate the action of heat and phosphorous insecticides.
Amitriptyline: In manic-depressive psychosis, depressed pa tients may experience a shift toward the manic phase if the are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. Th tranquilizing effect of TRIAVIL seems to reduce the likelihoo of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrin combined with local anesthetics, close supervision and carefu adjustment of dosages are required.
Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in pa tients who were treated with 1 g of ethchlorvynol and 75-15 mg of amitriptyline HCl.
Amitriptyline HCl may enhance the response to alcohol and th effects of barbiturates and other CNS depressants.
Concurrent administration of amitriptyline HCl and electroshoc therapy may increase the hazards associated with such therapy Such treatment should be limited to patients for whom it i essential.
Discontinue several days before elective surgery if possible Elevation and lowering of blood sugar levels have both bee reported.

ADVERSE REACTIONS: Similar to those reported with eithe constituent alone.
Perphenazine: Side effects may be any of those reported wit phenothiazine drugs: extrapyramidal symptoms (opisthotonus oculogyric crisis, hyper-reflexia, dystonia, akathisia, dyskinesia ataxia, parkinsonism) can usually be controlled by the cor comitant use of effective antiparkinsonian drugs and/or by re duction in dosage, but sometimes persist after discontinuation o the phenothiazine; skin disorders (photosensitivity, itching erythema, urticaria, eczema, up to exfoliative dermatitis); othe allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reverse epinephrine effect; hyperglycemia; endocrine disturbances (lac tation, galactorrhea, gynecomastia, disturbances of menstrua cycle); altered cerebrospinal fluid proteins; paradoxical excite ment; hypertension, hypotension, tachycardia, and EKG ab normalities (quinidine-like effect); reactivation of psychoti

rocesses; catatonic-like states; autonomic reactions, such as ryness of the mouth or salivation, headache, anorexia, nausea, omiting, constipation, obstipation, urinary frequency or incon- nence, blurred vision, nasal congestion, and a change in pulse ate; hypnotic effects; pigmentary retinopathy; corneal and enticular pigmentation; occasional lassitude; muscle weakness; nild insomnia. Other adverse reactions reported with various henothiazine compounds include blood dyscrasias (pancyto- enia, thrombocytopenic purpura, leukopenia, agranulocytosis, osinophilia); liver damage (jaundice, biliary stasis); grand mal onvulsions; cerebral edema; polyphagia; photophobia; skin igmentation; and failure of ejaculation.

mitriptyline: Note: Listing includes a few reactions not reported or this drug, but which have occurred with other pharmacologi- ally similar tricyclic antidepressant drugs. *Cardiovascular:* lypotension; hypertension; tachycardia; palpitation; myocardial nfarction; arrhythmias; heart block; stroke. *CNS and Neuro- nuscular:* Confusional states; disturbed concentration; dis- rientation; delusions; hallucinations; excitement; anxiety; rest- essness; insomnia; nightmares; numbness, tingling, and aresthesias of the extremities; peripheral neuropathy; incoordi- ation; ataxia; tremors; seizures; alteration in EEG patterns; xtrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth; lurred vision; disturbance of accommodation; constipation; aralytic ileus; urinary retention; dilatation of urinary tract. *llergic:* Skin rash; urticaria; photosensitivity; edema of face nd tongue. *Hematologic:* Bone marrow depression including granulocytosis; leukopenia; eosinophilia; purpura; thrombo- ytopenia. *Gastrointestinal:* Nausea, epigastic distress; vomiting; norexia; stomatitis; peculiar taste; diarrhea; parotid swelling; lack tongue. *Endocrine:* Testicular swelling and gynecomastia n the male; breast eniargement and galactorrhea in the female; ncreased or decreased libido; elevated or lowered blood sugar evels. *Other:* Dizziness; weakness; fatigue; headache; weight ain or loss; increased perspiration; urinary frequency; mydria- is; drowsiness; jaundice; alopecia. *Withdrawal Symptoms:* Abrupt essation after prolonged administration may produce nausea, eadache, and malaise. These are not indicative of addiction.

VERDOSAGE: The intravenous administration of 1-3 mg of hysostigmine salicylate has been reported to reverse the ymptoms of amitriptyline poisoning. On this basis, in se- ere overdosage with perphenazine-amitriptyline combinations, ymptomatic treatment of central anticholinergic effects with hysostigmine salicylate should be considered.

MERCK SHARP & DOHME

Addendum

A suggested four-point rating scale to help evaluate patient progress week-to-week or month-to-month when presenting symptoms include anxiety or agitation with depression.

Mood—degree of depression (facial expression, voice quality, conversation content).

1. Continued profound depression, feelings of hopelessness.
2. Feeling "blue," chronic pessimism, rare cheerfulness.
3. Appropriate cheerfulness, slight depression, diluted pleasure capacity.
4. Appropriate cheerfulness and optimism.

Psychomotor Activity—reflective of emotional pressure (hypoactive patient).

1. Immobile, not fulfilling daily responsibilities.
2. Generalized slowness, constant fatigue.
3. Appropriate motor activity in most instances.
4. Activity appropriate in degree and duration to environmental stimuli.

Performance—vocational.

1. Unable to perform at all.
2. Works intermittently with difficulty.
3. Full-time employment, moderate pride in achievements.
4. Full-time employment, functioning efficiently, deriving pleasure from achievements.

Anxiety Amelioration—in terms of motor, affective, autonomic and verbal phenomenon.

1. Panic, incessant movement, state of terror.
2. Moderate restlessness, pacing, moderate expression of fear.
3. Slight restlessness, slight affective expression of fear.
4. Calm, no restlessness, expression of fear (when it occurs) appropriate to severity of stress.

Amelioration of Symptoms

1. Symptoms unchanged or worse.
2. Fair, slight improvement, patient still plagued with symptoms.
3. Symptoms markedly reduced in intensity and frequency, able to cope.
4. All presenting symptoms gone.

Adapted from Lesse, S.: Anxiety, Its Components, Development and Treatment, Grune & Stratton, New York, 1970.

R.S.V.P.

She just doesn't respond to
ings. No interest. No energy.
iscouraged.

It may be mild depression.
ne needs help...and she needs it
ow.

Counsel and reassurance
ay suffice. But if you decide
pportive medication is indi-
ted, Ritalin can offer prompt
enefit.

Ritalin usually begins to act with the very first dose...boosts spirits and brightens mood...helps the patient get moving again. And Ritalin is generally well tolerated, even by older and convalescent patients. However, Ritalin should not be used for severe depression.

When Ritalin works, one prescription may be enough... to help provide an answer to mild depression.

Ritalin®
methylphenidate)
helps the patient
espond in mild depression*

talin® hydrochloride ©
ethylphenidate hydrochloride)

BLETS

INDICATION
Based on a review of this drug by the National Academy of Sciences-National Research Council and/or other information, DA has classified the indication as follows:
"Possibly" effective: Mild depression
Final classification of the less-than-effective indications requires further investigation.

NTRAINDICATIONS
rked anxiety, tension, and agitation, since alin may aggravate these symptoms. Also ntraindicated in patients known to be persensitive to the drug and in patients with ucoma.

RNINGS
alin should not be used in children under years, since safety and efficacy in this age up have not been established.
fficient data on safety and efficacy of long-m use of Ritalin in children with minimal in dysfunction are not yet available.
hough a causal relationship has not been ablished, suppression of growth (*ie*, weight n and/or height) has been reported with g-term use of stimulants in children. erefore, children requiring long-term rapy should be carefully monitored.
alin should not be used for severe depres-n of either exogenous or endogenous origin or the prevention of normal fatigue states.
alin may lower the convulsive threshold in ients with or without prior seizures; with or out prior EEG abnormalities, even in ence of seizures. Safe concomitant use of iconvulsants and Ritalin has not been ablished. If seizures occur, Ritalin should discontinued.
cautiously in patients with hypertension. od pressure should be monitored at appro-ite intervals in all patients taking Ritalin, ecially those with hypertension.
g Interactions
lin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.
Usage in Pregnancy
Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence
Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS
Patients with an element of agitation may react adversely; discontinue therapy if necessary. Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS
Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.
In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION
Adults
Administer orally in divided doses 2 or 3 times daily, preferably 30 to 45 minutes before meals. Dosage will depend upon indication and individual response.
Average dosage is 20 to 30 mg daily. Some patients may require 40 to 60 mg daily. In others, 10 to 15 mg daily will be adequate. The few patients who are unable to sleep if medication is taken late in the day should take the last dose before 6 p.m.

HOW SUPPLIED
Tablets, 20 mg (peach, scored); bottles of 100 and 1000.
Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak blister units of 100.
Tablets, 5 mg (pale yellow); bottles of 100, 500 and 1000.
Consult complete product literature before prescribing.

s drug has been evaluated as possibly effective for this indication. See brief prescribing information.

C I B A

This man will self-destruct...

ALCOHOLISM
shortens the abuser's life-span by 10 to 12 years*

Private problem/ Public menace

Besides having a shortened life expectancy, the alcoholic is roughly twice as likely to develop hypertension, ulcers, or cerebrovascular disease; 29 times as likely to develop cirrhosis of the liver; and 58 times as apt to commit suicide as the nonalcoholic. Moreover, an estimated 28,000 automobile deaths each year involve drinking drivers, and alcohol addiction, directly or indirectly, causes almost half of all the crimes in this country.

ANTABUSE® (disulfiram) when he's ready for help

For almost 25 years, ANTABUSE has proved its effectiveness as a medical adjunct in the management of alcoholics who are motivated to recover. ANTABUSE offers strong deterrent action to help them maintain sobriety and participate in a total treatment program, including supportive measures such as psychotherapy and/or concerned people, agencies, or organizations (e.g., Alcoholics Anonymous).

When you prescribe ANTABUSE and the alcoholic patient accepts it, he strengthens his resolve to stop drinking with each daily tablet he takes. If he drinks while the ANTABUSE effect remains in his bloodstream, he will become intensely ill. **The patient must be given a clear and detailed account of the effects of ingesting even a small amount of alcohol after he has taken ANTABUSE, and must be told that such effects may occur even up to 14 days after the last dose.** This factor deters impulsive drinking, shores up the patient's resolve, and helps enforce his sobriety. And, since ANTABUSE is nonhabituating, there's no chance of cross-addiction... a decided advantage in helping the motivated alcoholic stay on a long-term rehabilitation program.

*According to the National Institute on Alcohol Abuse and Alcoholism, alcohol abusers are estimated to shorten their life-span by an average of 10 to 12 years.

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE® (disulfiram) In Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

ANTABUSE®
Brand of DISULFIRAM

A strong deterrent for the alcoholic who doesn't want to drink

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

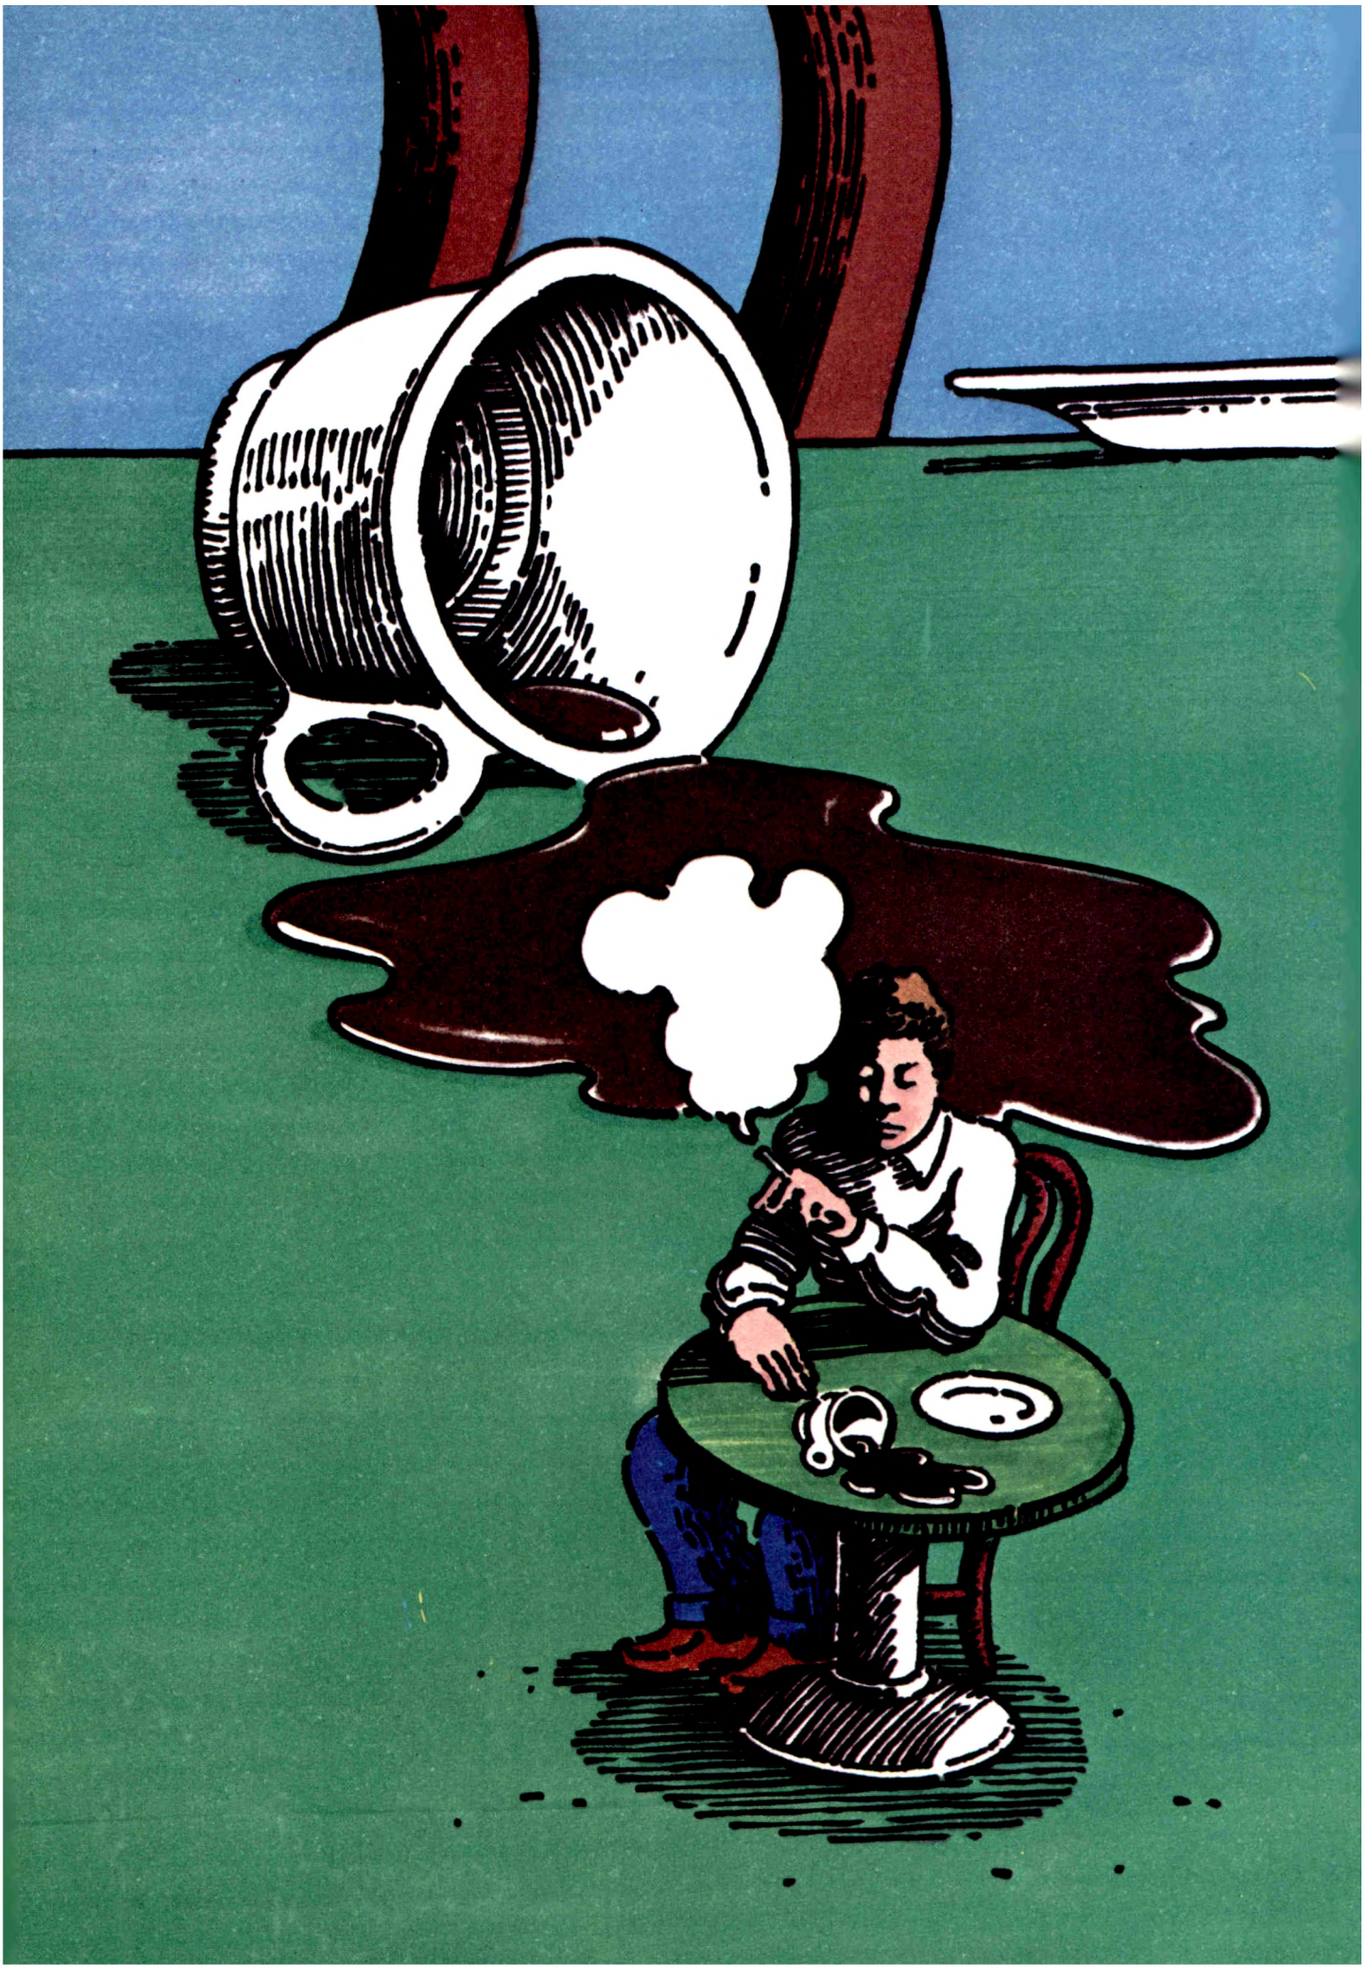
NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.



MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

Alcoholism/**ANTABUSE®** (disulfiram)

Ayerst® AYERST LABORATORIES

HEL ETI N HIS PERSPECTIVE ON REALITY

With effective management of psychotic symptoms

- Decreases delusions, auditory and visual hallucinations
- Lessens unusual thought content, paranoid ideation
- Allays underlying fear, anxiety and tension
- Controls hostility
- Calms hyperactive behavior
- Reduces emotional withdrawal

Before prescribing, see complete prescribing information including dosage and symptoms and treatment of overdosage, in SK&F literature or *PDR*.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

©1967, 1968, 1969 SmithKline Corporation

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudoparkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate, 30 mg./ml. and 100 mg./ml.

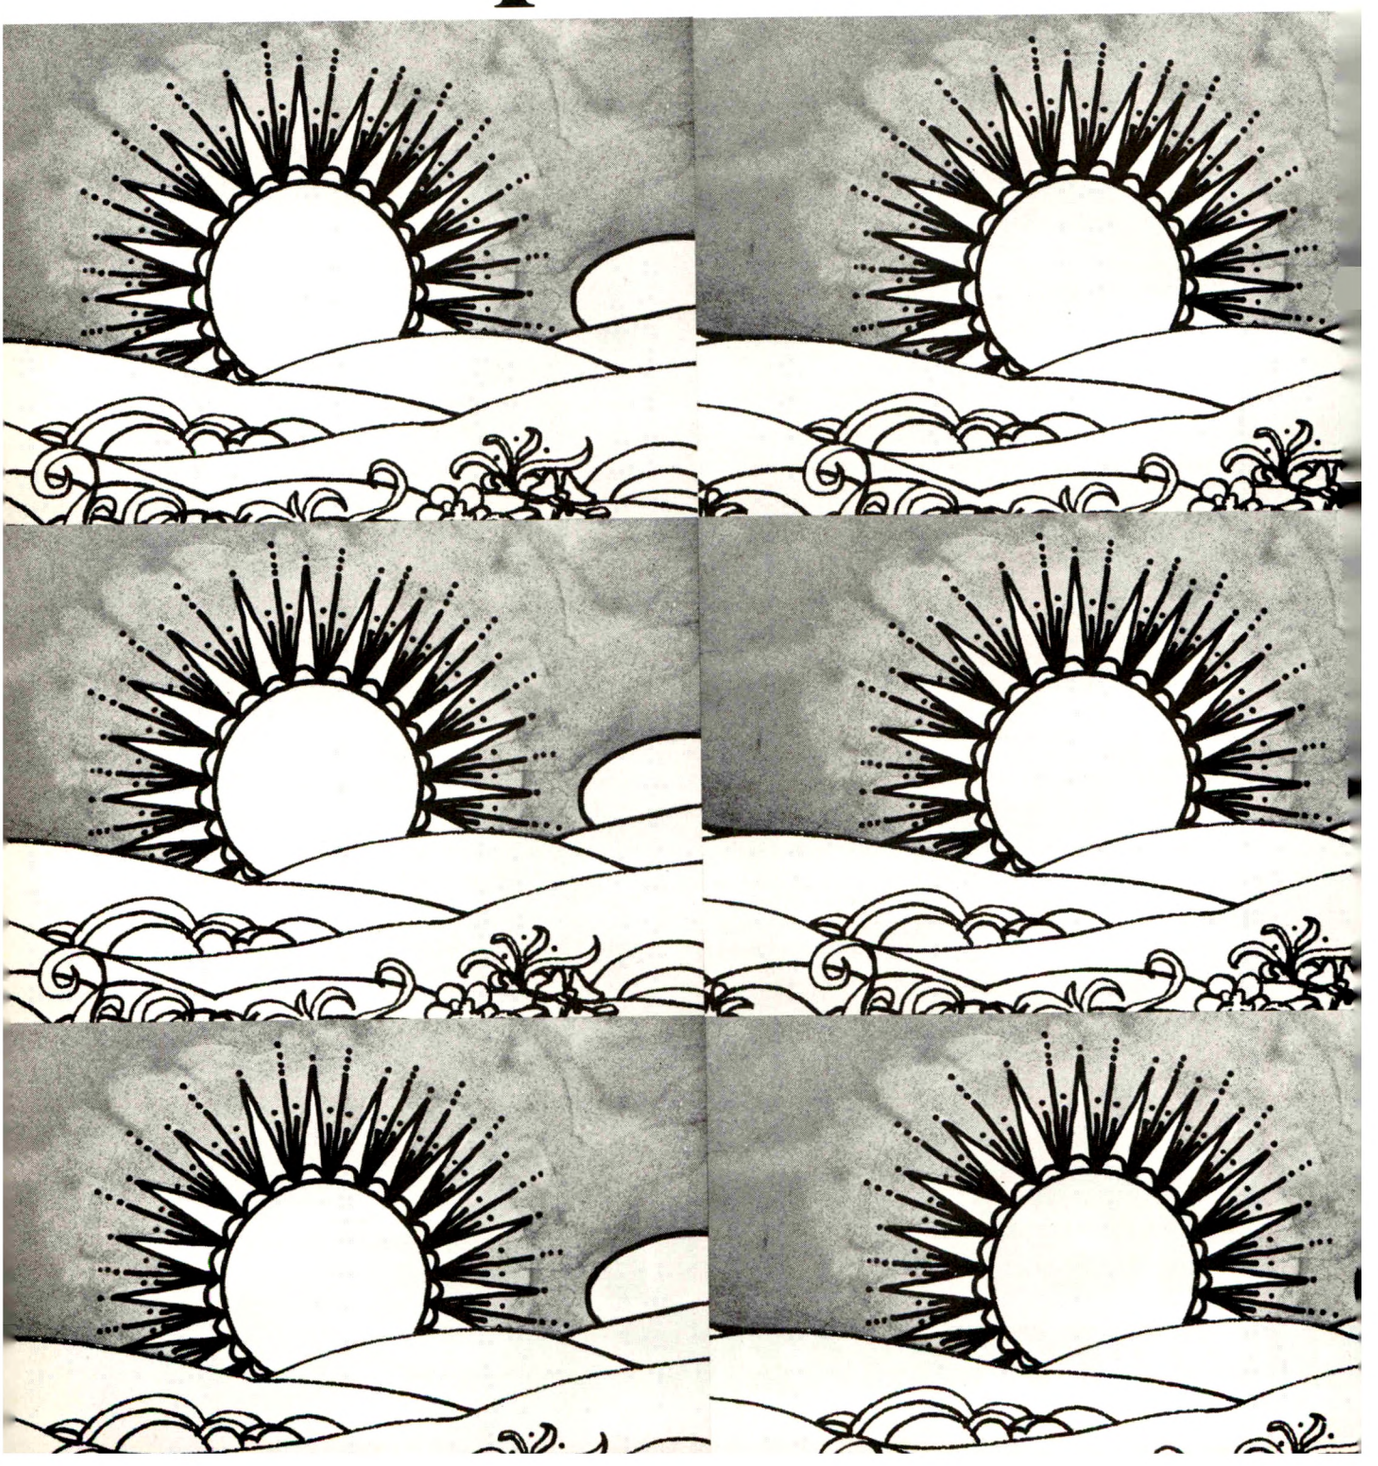
SK&F



THORAZINE®

brand of

C L P OMAZI E

Tablets:
50 mg. of the HCl

The new-day constant for drug-induced parkinsonism:

ARTANE®
TRIHEXYPHENIDYL HCl

Non-cumulative action makes each day of therapy a new day

That's why ARTANE is ideally suited for the patient on long-term phenothiazine therapy. In economical tablets or SEQUELS Sustained Release Capsules*, it offers you *more* than the rapid reversal of extrapyramidal symptoms.

Usually there is no drug buildup to cause undue toxicity in prolonged therapy. Minimal atropine-like side effects. Accurate dosage titration in adjunctive use. And, to minimize missed doses and anxiety in outpatient therapy— one-dose *all-day* control or prevention with SEQUELS.*

For hospitalized or ambulatory patients, ARTANE has the "constant" they need. Effective *non-cumulative* action.

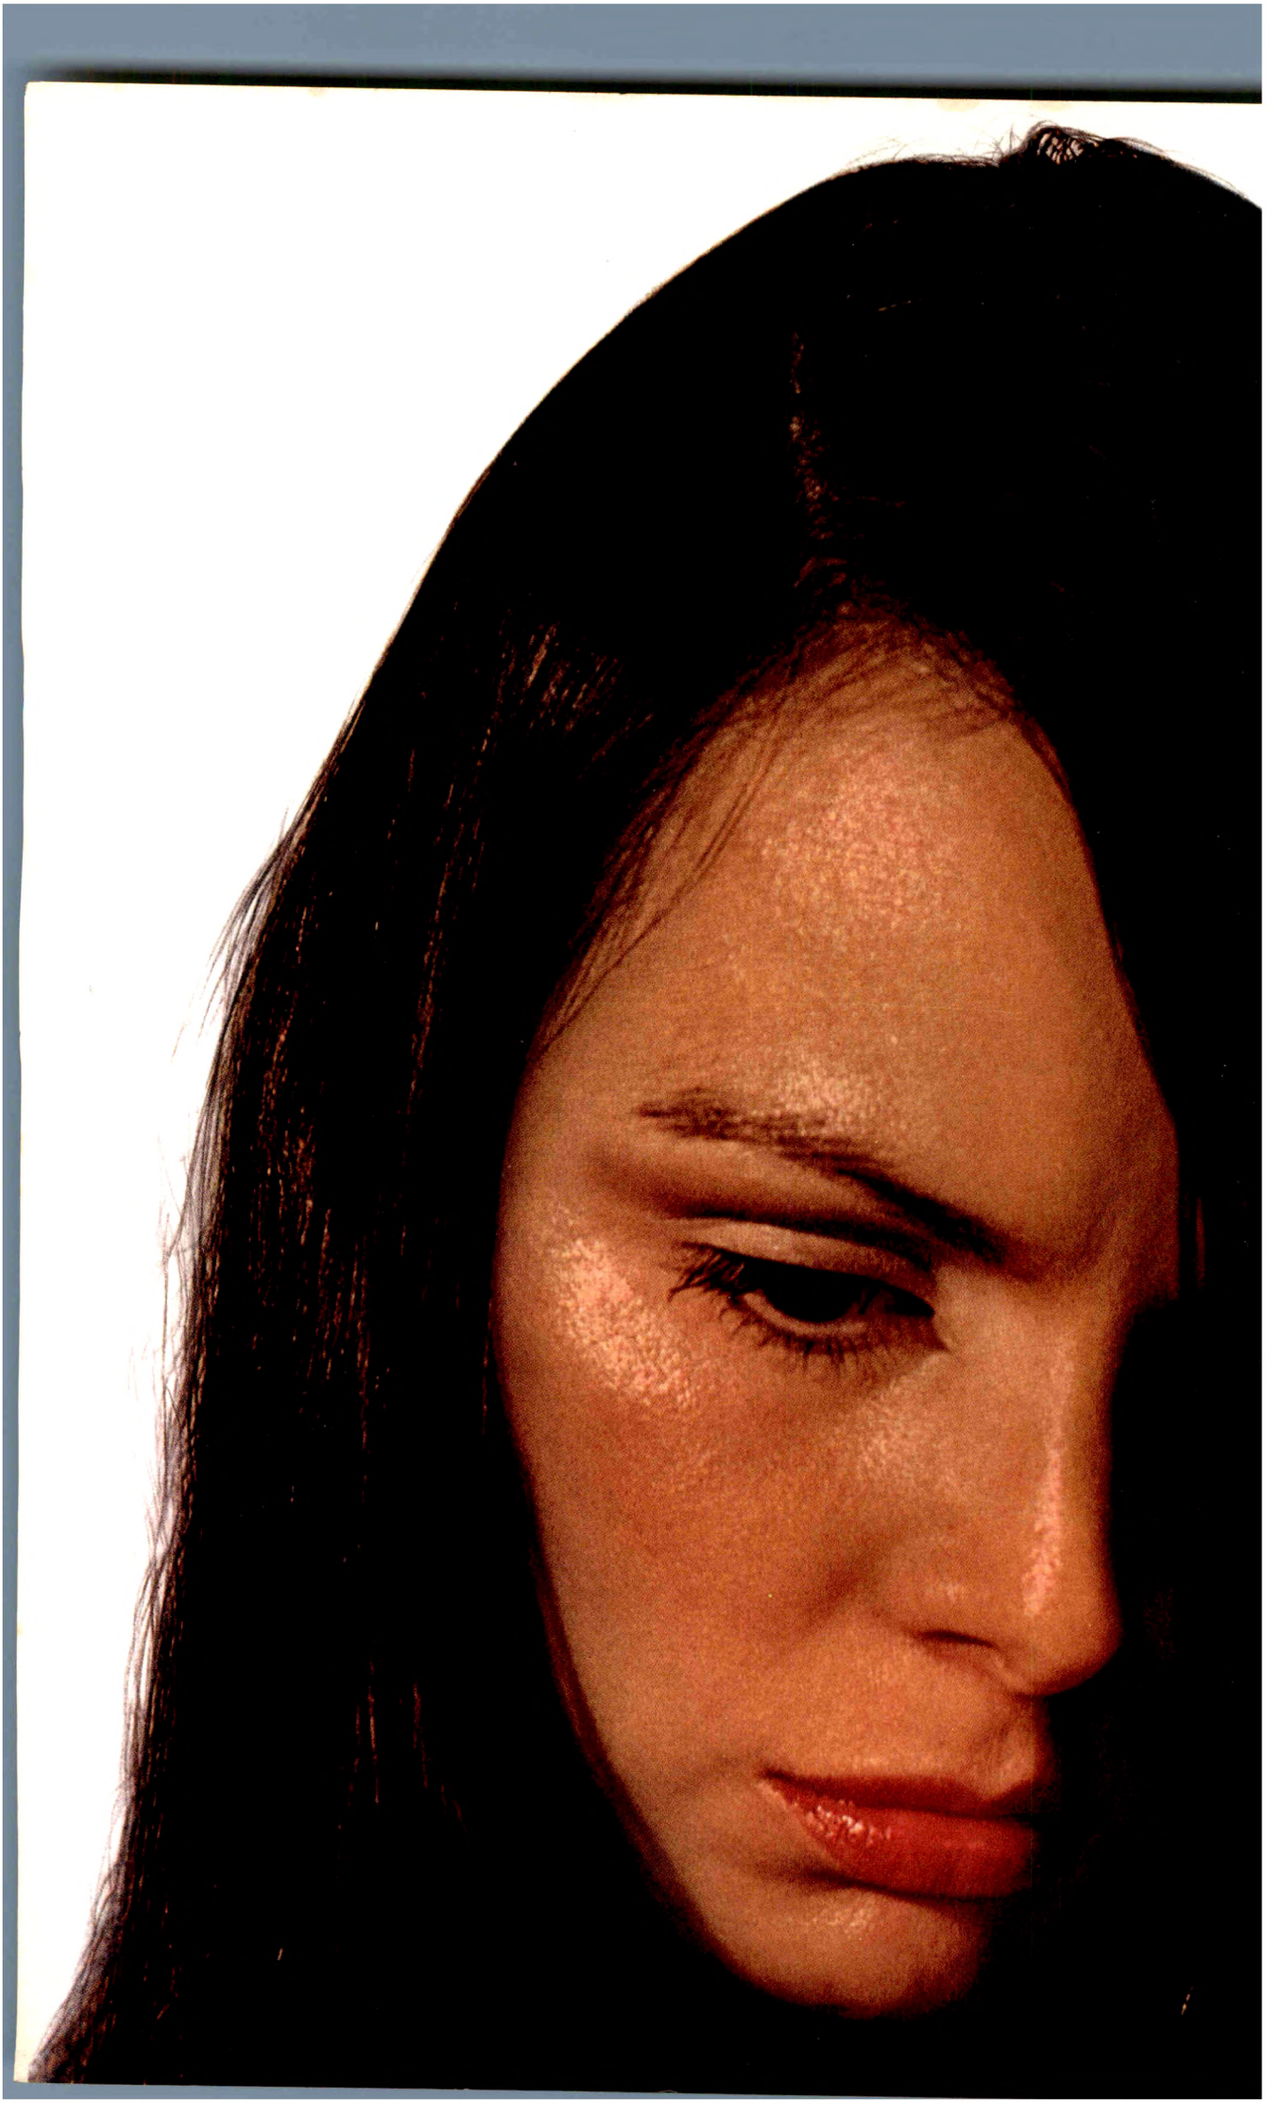
Tablets—2 mg, 5 mg; Elixir†—2 mg/5 cc or SEQUELS® Sustained Release Capsules—5 mg.

Tablets and Elixir Indications: FDA has evaluated this drug as Effective as an adjunct in the therapy of the indications listed below under SEQUELS.

***INDICATIONS FOR ARTANE SEQUELS:**
Based on a review of this drug in sustained release form by the National Academy of Sciences-National Research Council and/or other information, FDA has classified the indications as follows: Probably effective as an adjunct in the therapy of all forms of parkinsonism (postencephalitic, arteriosclerotic, and idiopathic) and for use in the prevention or control of extrapyramidal disorders due to central nervous system drugs such as reserpine and phenothiazines.

WARNING:
Patients to be treated should have a gonioscope evaluation and close monitoring of intraocular pressures at regular periodic intervals.

Precautions: Patients with cardiac, liver or kidney disorders or with hypertension should be maintained under close observation. In long-term therapy, take care to avoid allergic and other untoward reactions. Use with caution in patients with glaucoma, obstructive disease of the gastrointestinal or genitourinary tracts and in elderly males with possible prostatic hypertrophy. Geriatric patients require strict dosage regulation. Incipient glaucoma may be precipitated.



Adverse Reactions: Such effects as dryness of mouth, blurring of vision, dizziness, nausea or nervousness will be experienced by 30 to 50 per cent of patients. (These tend to lessen and can often be controlled by adjusting dosage.) Isolated instances of suppurative parotitis, skin rashes, dilation of the colon, paralytic ileus, delusions, hallucinations and paranoia (1 doubtful case) have been reported. Patients with arteriosclerosis or with a history of idiosyncrasy to drugs may exhibit mental confusion, agitation, disturbed behavior, or nausea and vomiting. If a severe reaction occurs, discontinue drug for a few days, then resume at lower dosage. Psychiatric disturbances can result from overdosage to sustain euphoria. Side effects of any atropine-like drugs include constipation, drowsiness, urinary hesitancy or retention, tachycardia, dilation of the pupil, increased intraocular tension, weakness, vomiting and headache.

†Lime-mint flavored, with 0.08% methylparaben, 0.02% propylparaben, and 5% alcohol as preservatives.

This drug in sustained release form has been evaluated as probably effective. See Brief Summary.

too anxious to listen... too depressed to respond

Mellaril®
(thioridazine)

for moderate to severe mixed anxiety-depression*

***Indications:** Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:
Effective: The management of manifestations of psychotic disorders.
"Probably" effective: The relief of symptoms of neurotic depressive reaction; and control of moderate to severe agitation, hyperactivity, or aggressiveness in disturbed children.
"Possibly" effective: Alcohol withdrawal syndrome, intractable pain, psychoneuroses, senility.
Final classification of the less-than-effective indications requires further investigation.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascul System*—ECG changes (see *Cardiovascular Effects* below). *Other*—A single cas described as parotid swelling.

The following reactions have occurred with phenothiazines and should b considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralyt ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact derm titis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thromb cytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Feve laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundic biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electr cardiogram, including prolongation of Q-T interval, lowering and inversion T-wave, and appearance of a wave tentatively identified as a bifid T or a wave have been observed with phenothiazines, including Mellaril (thiorid zine); these appear to be reversible and due to altered repolarization, n myocardial damage. While there is no evidence of a causal relationship b tween these changes and significant disturbance of cardiac rhythm, sever sudden and unexpected deaths apparently due to cardiac arrest have o curred in patients showing characteristic electrocardiographic change while taking the drug. While proposed, periodic electrocardiograms are n regarded as predictive. Hypotension, rarely resulting in cardiac arres *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dyston reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, mu cular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent ar sometimes irreversible tardive dyskinesia, characterized by rhythmical invo untary movements of the tongue, face, mouth, or jaw (e.g., protrusion tongue, puffing of cheeks, puckering of mouth, chewing movements) and some times of extremities may occur on long-term therapy or after discontinuatio of therapy, the risk being greater in elderly patients on high-dose therap especially females; if symptoms appear, discontinue all antipsychoti agents. Syndrome may be masked if treatment is reinstituted, dosage increased, or antipsychotic agent is switched. Fine vermicular movement of tongue may be an early sign, and syndrome may not develop if medica tion is stopped at that time. *Endocrine Disturbances*—Menstrual irregular ties, altered libido, gynecomastia, lactation, weight gain, edema, fals positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical rea tion, including excitement, bizarre dreams, aggravation of psychoses, an toxic confusional states; following long-term treatment, a peculiar skin-ey syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Future of Psychoanalytic Therapy

BY JUDD MARMOR, M.D.

The author believes that in the years ahead psychoanalysis will move increasingly toward an open-system biosocial perspective incorporating aspects of field theory, communications and information theory, and general systems theory. There are important implications in this for therapy: while long-term psychoanalytically oriented therapy along classical lines will still be needed for some patients, the analyst should make use of some of the newer techniques (including behavior therapy) that aid in amelioration of symptoms. The author also believes that changes are needed in the training of psychoanalysts; integrating psychoanalytic institutes within academic settings would be especially useful because the services of other behavioral scientists would be readily available to aid in the training of analytic candidates.

CONTRARY TO POPULAR ASSUMPTION, psychoanalysis, either as theory or as technique, has not been a fixed entity at any time in its history. Throughout his life Freud was engaged in a constant effort to bring his theories into more accurate alignment with the scientific models of his time as well as with the observed data of human thought and behavior. Beginning with Ferenczi and Rank and continuing to the present day, individual analysts have been experimenting with modifications in technique. Nonetheless, certain fundamental aspects of Freud's contribution have remained generally accepted by all psychoanalysts.

On the theoretical side, there has been no wavering from the conviction that human behavior is motivated, that our personalities are shaped by the interplay of biological potentials and life experiences, that functional psychiatric disturbances are the result of developmental vicissitudes and contradictory and conflictual inputs and feedbacks, and that early childhood experiences are of special significance in shaping subsequent perceptions and reactions in later life. Regardless of how various theoretical schools of psychoanalysis may differ from one another, I believe that all would subscribe to the foregoing essential elements.

On the therapeutic side, all schools of psychoanalysis aim at basic personality modification by increasing the patient's awareness of his unconscious motivations and conflicts. All place emphasis on the techniques of free association and dream interpretation in the pursuit of this goal, and all share the conviction that the way in which the interpersonal relationship between the analyst and the patient is handled and interpreted is a crucial factor in the therapeutic process. It is worth noting that although adherents of the various psychoanalytic schools of thought differ sharply over what constitutes the best or most "correct" interpretation of the underlying psychodynamics, they all share the assumption that making the correct cognitive interpretation to the patient is a core factor in the therapeutic process.

As the years have passed, however, the classic psychoanalytic model has undergone a number of modifications, and the line of demarcation between psychoanalytic treatment and other forms of dynamic psychotherapy has been blurred. Glover (1) found that this had occurred as early as the late 1930s in his investigation into psychoanalytic practices current in 1939, and Cushing (2), reporting for an official committee of the American Psychoanalytic Association in 1952, stated that after a four-year effort to achieve a consensus the committee had been unable to arrive at any clear-cut criteria for differentiation between psychoanalysis and psychoanalytic psychotherapy. More recently, a study conducted by Tabachnick (3) among Fellows of the American Academy of Psychoanalysis reconfirmed the existence of widely varying patterns of technique among contemporary psychoanalytic practitioners.

INCREASING FLEXIBILITY OF TECHNIQUE

There is no doubt that although there are still those who continue to adhere rigidly to the original therapeutic

Read at the 18th annual meeting of the American Academy of Psychoanalysis, Honolulu, Hawaii, May 5, 1973.

Dr. Marmor is Franz Alexander Professor of Psychiatry, University of Southern California School of Medicine, 2025 Zonal Ave., Los Angeles, Calif. 90033.

technique recommended by Freud, more and more analysts have begun to modify their techniques in a number of ways. Thus they often see their patients two or three times weekly instead of four or five. Many patients are seen sitting up; there is less rigid insistence on the use of the couch. Relatives are interviewed and occasionally even seen conjointly with the patient instead of being strictly excluded, as they were formerly. In contrast to the old dictum that no major life changes were to be permitted for the duration of the analytic process, many analysts not only allow but even encourage their patients to make basic changes in their life patterns when these changes seem rational and constructive. Finally, many psychoanalysts have begun, in general, to feel more free to enter into active communicative exchanges with patients instead of remaining bound to the incognito "neutral mirror" model of relative silence and impassivity.

One important consequence of this trend toward increasing flexibility in technique has been a growing interest in the process of the psychotherapeutic transaction, in contrast to the former preoccupation with its ideational or verbal content. Research into the nature of the psychotherapeutic process (4–6) has begun to make it clear that although cognitive understanding as administered via interpretive "insight" is a valuable adjuvant and facilitator of therapeutic change, it is by no means a sine qua non for such change. Considerable evidence has accumulated to indicate that the psychotherapeutic process is a learning process; what is most relevant to this process, however, is not so much the specific historical correlations between past experiences and current reactions as it is the acquisition of new models of behavior, thinking, and feeling. Moreover, these new models are not always achieved cognitively and consciously; as often as not they are acquired subtly, as a result of overt or covert suggestion, unconscious identification with the therapist, corrective emotional experiences in the interaction with him, and a kind of operant conditioning via implicit or explicit expressions of his approval or disapproval. In this process, the nature and quality of the patient-therapist interaction, the real personalities of both patient and doctor, and the degree of faith, hope, trust, and motivation that the patient brings to the therapeutic situation are of paramount importance in enabling the new learning to take place successfully.

These factors obviously also encompass what psychoanalysts refer to as the transference and countertransference aspects of the psychotherapeutic relationship. In contrast to former concepts that regarded analysis as something that the analyst did to or for the patient, the newer views take cognizance of the active and mutual transaction that takes place between patient and analyst.

While psychoanalytic therapy has been evolving in this way, however, it has begun to face a serious challenge from other psychotherapeutic approaches. A wide variety of behavioral techniques have emerged, all presumptively based on Pavlovian, Hullian, or Skinnerian theories of conditioning and all claiming a high rate of success in ameliorating neurotic symptoms, particularly phobias. These techniques, in contrast to psychoanalysis, tend to eschew cognitive awareness. Their emphasis is strictly on behavioral modification; the subjective problems, feelings, or thoughts of the patient are considered, if not unimportant, at least irrelevant to the psychotherapeutic process.

Another major psychotherapeutic trend, focusing neither on cognitive awareness nor on behavior but rather on feeling states, has been the enormous profusion of so-called Gestalt therapies, encounter groups, marathons (nude or otherwise), and a variety of techniques based on Eastern philosophies and involving transcendental meditation, Zen, Yoga, and the like.

Still another trend leans heavily on advances in technological and communicative techniques as they apply to human behavior. Thus we have witnessed a growing therapeutic use of tape-recorders, movies, videotapes, computers, and electrical stimulating and shocking devices. More recently, biofeedback techniques are being widely explored in an effort to achieve control of both voluntary and autonomic nervous system mechanisms.

Group therapies of many types have been occupying an increasingly important role in the psychotherapeutic spectrum during the past 25 years. Analytic group therapy has been conducted within Freudian, neo-Freudian, and Kleinian orientations; other approaches have invoked psychodrama, sociodrama, transactional gametherapy, and behaviorally oriented role playing or rehearsal.

A number of therapies have leaned heavily on the abreaction-cure theory that Freud initially propounded and later discarded. Among these are Dianetics and its pseudoreligious successor, Scientology, which enables its subjects to recapture presumed intrauterine memories and traumata, and Primal Scream Therapy, which (more modestly!) claims to recover memories only back to the moment of birth. In both of these approaches the recovery of such presumptive memories, together with the release of the associated buried emotions, is supposed to achieve a dramatic cure. The equally dramatic and rapid "cures" of lifelong personality disorders in five or ten sessions with LSD and other psychoactive drugs (amphetamines, barbiturates, carbon dioxide, etc.) that were being widely reported a few years ago were similarly based on the abreaction hypothesis.

UNIQUENESS OF THE PSYCHOANALYTIC APPROACH

Faced with these challenges, the question of what the future holds for psychoanalytic therapy is a valid and realistic one. There are some who argue that psychoanalysis is passé, that its theoretical constructs are outmoded, that it is a dubious therapeutic technique at best, and that its costliness in both time and money can no longer be justified in the face of newer and more effective techniques for symptom amelioration. On the other hand, there are others who continue to insist not only that classical Freudian psychoanalysis is the only basic science of

human behavior, but also that, if it is practiced in accordance with Freud's original precepts, it is still the best therapeutic instrument available for achieving fundamental characterological change.

I have no doubt that the broad concepts underlying the psychoanalytic approach, as I have outlined them, are fundamentally sound and demonstrably valid, and I know of no other technique of psychological investigation as capable of elucidating the subtle complexities of man's subjective inner life. But if psychoanalysis, as a therapeutic method, is defined in terms of a four-to-five-times-a-week, long-term dyadic technique, requiring the couch, focusing heavily on primary process material, and aiming at the promotion of transference regression and the revival of the so-called infantile neurosis, then I, too, would be extremely dubious about its future. I believe that as time goes on this approach will be relegated primarily to investigative and training pursuits and that it will be used less and less frequently for therapeutic purposes.

The essence of the psychoanalytic contribution to therapy, I am deeply convinced, lies not in such technical rigidities but in the basic understanding that psychoanalysis enables one to bring to bear on a variety of therapeutic techniques. Only a sound grasp of psychodynamic principles can enable the psychiatrist to properly evaluate the nature of the patient's underlying conflicts, the strength of his ego-adaptive capacities in relation to his life stresses, and the quality of the therapeutic transaction to which he is most likely to respond favorably. Does the patient need individual or group therapy or both? Should he be seen conjointly with his significant other or not? Will pharmacotherapy facilitate or block his ultimate therapeutic growth? Will it be sufficient therapeutically to reduce or remove the patient's symptoms and/or the stresses in his life, or will it be necessary to aim at basic intrapsychic modifications of personality? Will the patient do better with a man or a woman therapist, with a younger or an older one, with a "cool" or a warm one? Does he require a giving and permissive approach or will he do better with a firm setting of limits?

I do not assume that in our present state of knowledge we psychoanalysts can always give precise answers to all these questions, but I do believe that a sound understanding of psychodynamics makes it possible for us to arrive at more approximately correct answers than any other approach I know of.

I do not underestimate the creative contribution that behavior therapies have made to our armamentarium of therapeutic strategies in the past two decades. I have no doubt that many of their technical contributions will be enduring ones. But in focusing primarily on the "conditioning" aspects of psychopathology and psychotherapy, not only do behavior therapists ignore intervening variables in the genesis of personality disorders, but they also tend to minimize or ignore other significant elements in the psychotherapeutic process, particularly the importance of central cognitive processes and the critical aspects of the interpersonal patient-therapist relationship (7). It is precisely in its appreciation of these subtleties, and in its capacity to explore central cognitive processes, that the psychoanalytic approach brings a unique depth of understanding to the nature of human psychopathology. Only an approach capable of explaining *both* the inner and outer aspects of human behavior offers the hope of giving us the kind of fundamental scientific answers on which rational preventive and therapeutic approaches can be built. It is for this basic reason more than any other that I believe the essence of the psychoanalytic contribution will be an enduring one, even though its ultimate forms will undoubtedly be modified with time.

LIMITATIONS TO DYADIC FREE-ASSOCIATION METHOD

It is my conviction that if psychoanalysis as a therapeutic method is to remain viable, psychoanalysts cannot and must not tie their professional identities to a monolithic model of treatment. Freud developed the classical model primarily as an investigative instrument for the exploration of the unconscious—a purpose for which it still has no equal. But the exploration of the unconscious and optimal psychotherapy are not necessarily synonymous. We all know that toward the end of his life Freud expressed grave doubts about the ultimate therapeutic efficacy of his method of treatment. Moreover, as I have suggested elsewhere (8), there are serious limitations to the purely dyadic free-associational method even with regard to the basic psychoanalytic goal of broadening the patient's field of self-awareness. Not everything that the patient is unaware of in himself necessarily exists within his unconscious because it may never have been registered by his perceptual system; consequently no amount of free association will bring such matters into consciousness.

Also, as Freud himself noted, free association is not always free. It is limited not only by the particular relational framework that exists between patient and therapist, but also by the specific values and expectations of the therapist as communicated by his nonverbal as well as his verbal reactions. The observations of the therapist, too, are limited by this field so that as a consequence certain aspects of the patient's mode of reaction may never come to his attention. Thus it may not only be helpful, but even essential for the achievement of his analytic goal, for the psychoanalyst to broaden his field of observation by bringing in significant others for interviews; for therapeutic interaction with the patient, as in conjoint marital or family therapy; or by placing the patient in a group situation where transference reactions with sibling surrogates, with peers of the same and opposite sex, and with other interpersonal figures can be brought to light.

Otherwise, patients can observe the rules of the free-associational dyadic model beautifully and be regarded as "perfect" analytic patients and yet fail to recognize or bring into the analysis those aspects of their maladaptive personality patterns which are creating interpersonal problems. I have elsewhere (8) referred to a patient

whose compulsive need to dominate a conversation was effectively hidden in the dyadic psychoanalytic model—where she was *supposed* to do all the talking—but became quickly apparent when she was placed in group therapy. Other examples are the patient whose cooperative and compliant relationship with a respected analyst may never bring to light his subtle, unconscious ways of derogating sibling surrogates or the patient whose paranoid distrust of others is so totally rationalized that unless the analyst is able to obtain some outside information along the way its nonvalid basis may never come to light within the positive therapeutic alliance. Let us not forget that the most famous error in the history of psychoanalysis—Freud's belief that his hysterical patients had all been seduced by the parent of the opposite sex—went uncorrected until Freud was able to obtain incontrovertible evidence outside of the analytic situation that the "facts" his patients were reporting to him could not possibly be correct!

There are also stringent limitations in the indications for the strictly dyadic free-associational model. By and large, analysts prefer young, intelligent, articulate adults with reasonably good ego strength and sufficient economic resources to sustain an intensive, long-term therapeutic transaction. Such patients, however, are precisely the ones who are also apt to do well with other forms of treatment. Patients who are "too sick" are often rejected as poor risks for standard psychoanalytic therapy. Yet years ago analysts like Sullivan and Fromm-Reichmann demonstrated that psychoanalytic understanding could be used creatively and constructively in the psychodynamic treatment of schizophrenics and other deeply disturbed patients by modifying the standard technical requirements and working face-to-face in a participant-observer interaction with them. A few years later, Alexander and French and their colleagues at the Chicago Psychoanalytic Institute brilliantly described how psychoanalytic principles and understanding could be applied to shorter-term and less intensive therapeutic techniques with strikingly good results. Finally, the use of psychodynamic group therapies, marital therapies, and family therapies, all within the context of psychoanalytic understanding, have added significantly to our therapeutic potential.

These developments become all the more important when we consider the challenges with which psychoanalysts will be increasingly confronted in our changing socioeconomic milieu and in the face of future health insurance programs. The rapidly burgeoning societal demand for more equitable distribution of mental health care will put increasing pressure on psychiatry to abandon costly long-term, one-to-one psychotherapeutic techniques in favor of more economical short-term or group approaches.

IMPLICATIONS FOR INSURANCE COVERAGE

It may be all very well to argue—as both the American Academy of Psychoanalysis and the American Psychoanalytic Association have done—that long-term psychoanalysis, as a legitimate therapeutic approach, ought not to be excluded from any future national health insurance plan. But on what actuarial basis can we justify a treatment that may include four or five expensive visits per week for an indefinite number of years? There are those who point to renal dialysis as an example of an equally or even more expensive and "interminable" treatment that *has* been included in health insurance programs. This is true. But massive kidney failure is a relatively infrequent disorder, and its cost limits can be estimated more or less accurately. We can argue justifiably and analogously for including the costs of keeping chronic schizophrenics on maintenance programs indefinitely; the indications for such treatment are relatively clear-cut and the incidence of chronic schizophrenia in a population remains fairly constant and can be reasonably estimated from year to year.

Can we define with equal clarity the criteria for standard psychoanalytic treatment? Is there sufficient consensus about the indications for such treatment so that we can say what specific disorder or disorders warrant it? If there were, high cost alone would certainly not be a justification for denying sick patients access to an essential form of treatment. Unfortunately, however, psychoanalysts have generally asserted that almost everyone—at least everyone who is sufficiently articulate, intelligent, and motivated—could benefit from such treatment. But surely it cannot be our intention as psychoanalysts to insist that health insurance plans should pay for the comparatively healthy person who would like the luxury of extending the borders of his self-understanding.

There are some who argue that all of this is irrelevant. There are after all only a limited number of psychoanalysts in our country, and even if all their time were paid for by health insurance plans it would be actuarially feasible to provide this luxury. Perhaps so. But do we psychoanalysts seriously want to insist that we have the right to devote a lifetime of expensive training and not inconsiderable talent to the treatment *at government expense* of a relative handful of people who are not too seriously ill by our own admission (since if they were, they would not be considered suitable for such standard psychoanalytic treatment)? Society cannot be entirely blamed for insisting—if it is to foot the bill—that we make every effort to spread our talents more broadly among those whose needs are greater.

It may be asserted that the refusal to include classical psychoanalysis in health insurance plans will represent a serious loss for psychiatry and will deprive some patients of the opportunity to achieve maximum or optimum therapeutic benefit for their problems. That is a possibility. I suspect, however, that this is more an article of faith than of fact. I know of no hard data to support the conclusion that long-term, four-to-five-times-a-week psychoanalytic treatment produces superior ultimate results in terms of emotional growth and maturation than does long-term, twice-a-week, more flexible psychoanalytically oriented psychotherapy. I do believe, however, that long-term psychoanalytically oriented psycho-

therapy will continue to be needed and can be actuarially and socially justified; I hope that I will not be misunderstood as derogating it or advocating that we relinquish its use. There will always be deeply disturbed patients who have been so traumatized in their crucial early experiences with significant others that, until they have worked through their basic distrust and insecurity in the matrix of a repeatedly tested intimate and empathic psychotherapeutic relationship, they will simply be unable to accept or benefit from other therapeutic approaches. But even such patients may ultimately be able to extend their therapeutic growth by our making other parameters available to them later in their treatment. I am suggesting only that we psychoanalysts be both willing and able to use a flexible rather than a monolithic approach to those who consult us professionally.

NEED TO EXAMINE NEWER TECHNIQUES

Indeed, I would go a step farther and say that as psychoanalysts we should be examining with interest (and not with hostility) all the newer techniques that have been emerging in recent decades. Do they work? If they do, why do they work? And finally, if they work, are any of them capable of being incorporated into our own psychodynamic approach so that we can be of greater assistance to our patients? Feather and Rhoads (9), for example, recently reported on a way of ingeniously combining psychoanalytic concepts with behavior therapy by desensitizing their patients, not to the external anxiety-producing stimuli—as is usually done in behavioral therapies—but rather to the underlying unconscious conflictual drives and impulses from which the symptoms are believed to have been derived. Their reported successes merit further explorations along similar lines.

In short, in justice to our patients we simply cannot continue to ignore the shortcuts to symptom amelioration offered by some behavioral techniques; we must learn to make use of them when indicated. Many patients with sexual dysfunction, for example, deserve a trial with the Masters and Johnson approach to treatment of the couple's interpersonal sexual dynamics before the individual patient is engaged in several years of expensive and intensive exploration of his intrapsychic conflicts and complexes in an effort to psychoanalytically exorcise his or her underlying "castration" anxieties. Similarly, many patients with disabling phobias can now be restored to function in a relatively short time by behaviorally oriented techniques without our having to first put them on the couch for several years.

Such approaches do not preclude the additional use of intensive analytic therapy whenever our psychodynamic evaluation indicates its necessity. The psychoanalyst in such cases is no different from the internist whose patient comes to him, say, with a distressing diarrhea. The physician's first obligation is to do the careful studies that will enable him to diagnose the source of the problem. If the source is a relatively benign one, such as an exogenous food poisoning, simple symptom control by antidiarrheal medication and interdiction of the offending food may be all that is necessary. Should the diagnostic study reveal a more serious underlying disorder, the physician will address himself to that, of course, but at the same time he will do everything he can to control the patient's symptoms and alleviate his suffering.

In psychiatry we have a comparable situation in, for example, the middle-aged woman with a climacteric depression of psychotic proportions. The psychodynamic history may reveal a person who has an underlying restricted, compulsive personality, is sexually inhibited, has low self-esteem, an indifferent husband, and no outside interests, and who decompensated when her only son left home to get married. Few if any of us would consider trying to analyze such a patient without first trying to relieve her disabling depressive symptoms. Yet having done so, most of us would not consider the problem adequately dealt with if we did not try to do something afterward about the patient's underlying psychodynamic and interpersonal problems.

One reason why we psychoanalysts have tended to avoid dealing with neurotic symptoms in the same way has been the myth of symptom substitution. We have generally assumed that if we merely removed a symptom without dealing with its underlying causes a new symptom would inevitably appear in its place. As I have indicated (7), this traditional assumption is based on the closed-system psychodynamic "hydraulic" model that we inherited from Freud. If, however, personality dynamics are more accurately perceived within an open-system frame of reference, such a consequence is not inevitable. Removal of an ego-dystonic symptom may, on the contrary, produce such positive feedback from the environment as to result in major constructive shifts in the original conflictual pattern. Removal of a symptom may also lead to changes in self-perception with resultant ego-syntonic internal feedbacks and heightening of self-esteem, thus also contributing to positive restructuring of internal psychodynamics.

This latter point illustrates the necessity for psychoanalysis to modify some of its theoretical constructs if it is to be able to broaden its therapeutic perspectives. I will not dwell on this point at length because my focus in this essay is primarily on the therapeutic aspects of psychoanalysis. I began this paper, however, by pointing out that change is not alien to psychoanalytic theory, just as it is not alien to therapy. The shift from an id-oriented to an ego-oriented psychology, initiated by Freud himself in 1926 in "The Problem of Anxiety" and carried forward by Wilhelm Reich, Anna Freud, and Heinz Hartmann, the introduction of a more sophisticated cultural orientation by Horney, Fromm, Kardiner, and Erikson, and the development of an interpersonal framework by Sullivan and an adaptational one by Rado have all been steps in this direction. It is now becoming increasingly clear, I believe, that psychoanalysis in the years ahead will be moving more and more toward an open-system biosocial model, incorporating aspects of the field theory of Kurt Lewin, the communications and information theory of Shannon and Weaver, the cybernetic model of Norbert

Wiener, and the general systems theory of Von Bertalanffy. John Bowlby (10) pointed out the way in which our current psychoanalytic theories can be adapted to such a model in his superb volume *Attachment*; more recently, Emanuel Peterfreund (11) attempted to do something similar. I have no doubt that our psychoanalytic theories will eventually be brought into alignment with such current models in the behavioral sciences, which are based on the latest scientific evidence of how the brain (as the organ of what we call "mind") functions. The psychoanalytic theory of mind cannot continue indefinitely to be an abstraction with no connection to the main body of behavioral science theory.

TRAINING THE ANALYST OF THE FUTURE

What I have been saying also has important implications for how we will have to train the psychoanalysts of the future. If psychoanalysis is to continue to be the cutting edge of psychodynamic psychiatry, we can no longer afford to train our candidates primarily by exposing them to the past works of Freud and/or Horney, Sullivan, Rado, etc. Ours must be a living science and should be taught as one. This is not an easy thing to do, because we who are the teachers and who have ourselves been trained in the old tradition are not yet comfortable enough with the new body of knowledge to convey it easily to our students. And yet, despite the difficulties, it is imperative that we make the effort.

I am still of the opinion that integrating our psychoanalytic training institutes within academic settings would facilitate such a changeover, because we would then be able to borrow the talents of other behavioral scientists in the training of our candidates. Moreover, I believe it will be important to go beyond training our candidates only in a dyadic model of therapy. They must be taught how to apply their psychoanalytic understanding to other forms of therapy, particularly group, family, and marital techniques, so that they can more flexibly utilize the therapeutic modality that will most efficiently and effectively modify both the intrapsychic and the interpersonal aspects of the patient's life-system. The professional identity of the psychoanalyst of the future should depend on the theoretical sophistication and depth of understanding that he brings to every aspect of psychiatry not just on his being a technician who has mastered a single therapeutic technique. Such broadening of our professional identity can only increase our scientific stature as psychoanalysts and strengthen our future. To narrow our identity to that of a highly trained technician, on the other hand, will stringently limit our influence and jeopardize that future.

Psychoanalysis, with its deep concern for individual emotional growth, maturation, and self-realization, has been one of the principal guardians of the humanistic tradition in contemporary psychiatry. If we and those whom we are training can continue our own growth and development—in theory, training, and therapy—I am deeply convinced that the light of psychoanalytic understanding will illuminate the field of psychiatry as brightly and prestigiously in the future as it has in the past.

The Concept of Child Advocacy

BY JOHN F. MCDERMOTT, JR., M.D., WILLIAM M. BOLMAN, M.D., ALFRED M. ARENSDORF, M.D., AND RICHARD A. MARKOFF, M.D.

The authors examine the concept of child advocacy in historical perspective, describing its antecedents as reflected in law, education, welfare, and child labor. Although it is not yet realized in practice, child advocacy seems to represent the recognition by society that the developmental needs of its children are so important that they must be ensured as rights to be promoted and protected.

CHILD ADVOCACY, as articulated by the Joint Commission on Mental Health of Children (1), is a catchword for our field in the 1970s. As it is formulated, who could be against it? The intent of the concept is not simply to develop and reorganize a mental health delivery system for children (although this is an enormous task in itself) but also to create a national children's policy that guarantees optimal developmental conditions for all children. It is based on the underlying precept of rights of children, the idea that every child is *entitled* to the basic care and assistance he needs for optimum growth and development. It recognizes that not all parents have the means or capability to provide all the necessary care. So the strengthening of the complementary parental functions of society is required—a role that has been difficult for our governmental systems to carry out. As conceived in proposed legislation there would be a nationwide system of child advocacy at local, state, and federal levels.

Because the word "advocacy" is so broad, it can be subject to various interpretations and definitions. There is a real hazard that it may become simply another inspirational rallying cry for a short-lived evangelism rather than the beginning of a continuing national commitment. It might simply serve as a new lobby bandwagon for child mental health professionals to jump upon, or yet another transient federal grant program embarked upon without adequate consideration of the readiness of society to make it a lasting commitment.

For example, one professional recently stated: "At no previous point in our national history have we found the rhetoric of commitment to children coupled with a professional commitment to the 'whole' child, his family, and his community, extending beyond the territorial interests of separate professional disciplines" (2). But skeptics will point out that historical and social indicators seem against us, that protection of animals antedated protection of children; we still put more money into the protection of animals than of children, and have far more laws protecting business interests than children's interests. Nonetheless, much commentary has appeared in the recent literature on child advocacy as a result of the Joint Commission report (3–7).

This report will examine the concept of advocacy in historical perspective, so that we may look at society's current attitude toward children as a point along a scale of readiness to identify and deal with their needs. In this discussion, we will look particularly for antecedents of child advocacy among broader social attitudes as they are reflected in law, education, welfare, and child labor. If the concept is more than a fad for the 70s, we should be able to find a discernible pattern in history.

HISTORICAL PERSPECTIVES

The notion that childhood is only a recent invention is still startling to many. Of course we acknowledge that Freud called our attention to its special significance for our field only a few decades ago, but that the phenomenon of childhood itself is only 400 years old in Western culture seems incredible. But it is true: the world of fairy stories and special books, games, and toys is a characteristic of modern times. As in some present-day societies, children were regarded as infants until seven or eight years of age and thereafter as adults; initiation rites marked the passage from one to the other. Aries pointed out that, as late as the 12th century, European artists did not even attempt to portray childhood as a reality. Children were painted as miniature adults and wore adult clothing (8).

As for children's "rights," in the Middle Ages these were confined to primogeniture. This social attitude, which was intended to preserve the family structure and avoid competition among siblings, applied a specialness only to the first-born male. By and large, young children were regarded in part as pleasant or petlike animals and in part as defective or incomplete adults (9). The idea of childhood as a graduated developmental continuum simply did not exist, and infants were hurried along into adulthood as fast as possible. Children "just did not count" until they could participate in adult life.

There were a number of reasons for this. Probably the most important were the high mortality rate of children

The authors are with the Department of Psychiatry, University of Hawaii School of Medicine, Leahi Hospital, 3675 Kilauea Ave., Honolulu, Hawaii 96816, where Dr. McDermott is Professor and Chairman, Dr. Bolman is Professor, and Dr. Arensdorf and Dr. Markoff are Assistant Professors.

and the overall economic scarcity. It wasn't worth investing importance in someone who was apt to die before five years of age; one must wait until he not only survived but could earn his own keep. There was good reason for children to adopt adult roles early in order to better prepare them for life—a struggle for survival; because of these economic facts of life, adolescence was unknown.

The special nature of children began to be acknowledged in the 16th century. Children were given different kinds of clothes than their elders and their own toys and games. Thus the notion of childhood was expanded beyond infancy to include school age as a special developmental period. The important role of education has been emphasized in prolonging the period defined as childhood (10). Originally it was prompted by the monks, who recognized the importance of educating the young. In 1524, Martin Luther sent a letter to German municipalities urging upon them the duty of providing schools and upon parents the duty of sending their children to schools (11). Luther should be regarded here as an example of the many individuals whose foresight and leadership led them to recognize the special needs of childhood and to advocate social concern and intervention.

However, social interest remained adultomorphic for many more years; it focused mostly on guiding children's morals and reforming them from their "inborn" evil nature. This religious and moral interest in children has been especially characteristic of Judeo-Christian societies, including the United States. Here the advocate has shifted from the clergyman, who wanted to save the child from his own depravity, to the educator, who wanted to teach him the necessary skills to achieve success. The same objective seemed to pervade one other pioneering advocate function the church had performed for children who had been abandoned—caring for them in orphanages.

Child-Rearing Practices

In a society where physical force was accepted among adults, whippings were used liberally with children and fear was a valued and essential "virtue" to be instilled in a child. Growing up was indeed a battle between the young and the old in which the parents had the power of life or death over their offspring and children had no legal recourse against physical abuse, to say nothing of neglect. In any authoritarian society, children's needs tend to be seen as identical to those of the parent, and thus they are little more than chattels before the law. Of course, adults themselves had little self-determination in those days, as most relationships were authoritarian ones. This may be one reason why parents reacted so violently to independent and self-assertive behavior in children: adults then were very childlike themselves in this area of social maturity. It is interesting to note that the concept of public welfare for unemployed adults also emerged in the 16th century. Social awareness of different categories and degrees of helplessness was perhaps developing.

The long-standing lack of rights for children is well illustrated by the English Poor Law of 1601, which established the *virtue* of child labor and authorized the exploitation of children as miniature and inexpensive workers. This was rationalized as a way to prevent idleness and vagrancy (12), and to keep the relief rolls down. The Industrial Revolution, which will be discussed later as a long-range turning point in the child's favor, in its early days systematically perfected the use and abuse of child labor. And while labor statutes were finally enacted in England and the United States in the 19th century, representing public recognition of the need to protect children from exploitation if society was to advance, the *needs* of children continued to be neglected.

MODERN TIMES

In the 19th and 20th centuries several trends in social attitudes to children became evident. First, medical and public health advances began to reduce infant mortality so that we could consciously determine the size of our families and could afford to become attached to our children, knowing they were likely to survive and return the attachment (13). There has also been an increasing rate of social concern over the needs of children as part of a broad progressive social reform movement. In particular the National Child Labor Committee, founded in 1904, played a prominent role in defending children's rights. This group was a politically effective lobby group with a broad political base of individuals who believed that a healthy and normal childhood was not only the rightful heritage of all children but also essential for the development of socially useful adults.

Underlying the increased social concern for children that characterizes the modern period has been the increase, particularly in the United States, in the productivity of labor and the general wealth of society. These factors permit children to be economically nonproductive for longer and longer periods of time; this, in turn, lays the basis for affectional rather than instrumental or economic attitudes toward children. The growth of organized labor, for example, has been a major factor in the curtailment of child labor.

The White House Conference on Children in 1909 issued the first of many public statements regarding the commitment of this nation to the needs of all its children. President Theodore Roosevelt, an ardent conservationist, supported the creation of a federal bureau to collect information and to disseminate results of scientific research on the care and protection of children. Florence Kelly and Lillian Wald proposed that this "National Commission for Children" perform functions similar to what the U.S. Department of Agriculture did for farm life, that is, to make available and interpret the facts concerning the physical, mental, and moral conditions and prospects of American children. Such views, which closely resemble those of the present day, led to the formation of the U.S. Children's Bureau, which served a major advocate function until its recent reorganization. Later, after the 1930 White House Conference on Children, juvenile courts and child guidance clinics were set up, also presumably in an advocate role; a number of these still exist.

However, a number of critics have pointed out that none of these agencies expanded into comprehensive service networks or stirred up a continuing national commitment to children. Occasionally charismatic figures such as Father Flannigan of Boys Town caught the nation's attention and support, but as with all individual movements, this model failed to develop into a broad-based ongoing commitment. Perhaps the most interesting trend has been that of public education and the school's responsibility for the child. The war between "school and hearth" (14) raged during the last century as well as this; teachers were accused of usurping the rights of the home in areas of discipline and sex education. The state, having replaced the church as the child's advocate, has not been able to decide whether it should be concerned with the child's character, and, if so, in what direction.

DISCUSSION

This incomplete and highly selective historical view leaves many more questions than answers. However, there are some suggestive leads that may merit closer consideration.

First are the two rough dates, 1500 and 1800, that appear as turning points marking three major periods. The first period is that before the 16th century, when the very concept of childhood did not exist. The second period is the three centuries between the 16th and 19th century, when childhood began to acquire an identity and was recognized as having an existence of its own. In this period, childhood acquired sets of attitudes, customs, and behaviors toward children including special clothes and toys as well as recognition of the special needs for support, guidance, and education. Although many of these ideas were religion-oriented and adultocentric, with time they became more scientifically based and child centered. Third is the period from the 19th century to the present, when children have come to be seen as so important to the welfare of the state that social legislation has emerged to protect them from exploitation (as in child labor laws) and to promote their development (as in compulsory public education and the creation of the Children's Bureau). Looked at in the perspective of these historical underpinnings, child advocacy appears to be much more substantial than a passing fad.

If there is any one thing that qualitatively differentiates child advocacy from earlier movements, it is that the goals of child advocacy tend to be phrased in terms of the rights and interests of children themselves rather than in terms of society's self-interest in the reform of child care. This is not to say that earlier concerns with the welfare of children have been totally adult centered. But the steady increase in a child-centered approach seems to have produced, in dialectic fashion, a qualitatively new level of social concern in the current movement for child advocacy.

Although we are not qualified to discuss the relationships between historical and economic forces and changes in social attitudes toward children, our review seems to be a clear reminder that freedom from economic dependence is necessary before a culture can liberalize its attitudes toward children. In 16th-century Europe the economic breakthrough was the large-scale development of commerce; in 19th-century England the event was the Industrial Revolution. Both led to profound social and cultural changes that included new attitudes toward children. If we consider societal values for children relative to other forces, we may be helped to put today's stress on child advocacy in perspective.

A major finding in this historical review is the discrepancy between individual and social attitudes toward children. At least from the time of Jesus, farsighted and charismatic leaders have urged social concern for children and their development; this went on centuries before such ideas were adopted. Yet societies often seem principally concerned with those who make trouble, such as delinquents, or those who elicit sympathy through visible handicap or illness. Predictably this has led to sporadic bursts of interest with either a punitive or a sympathetic approach and little follow-through, resulting in irregular cycles of interest and neglect. Political cycles also contribute to this phenomenon by election-year interest (and perhaps even funding) followed by several years of neglect and failure to follow through.

Of greater importance are social attitudes that reflect the unreal and contradictory conceptualizations of children that have been particularly evident throughout recent history. In particular, Rexford explained the ambivalence of society toward children as the result of their awakening unconscious urges and conflicts in adults that are denied and projected onto the youth of that society (15). Children and youth are therefore eternal reminders of dependency, unfulfilled longings, and the sexual and aggressive problems of mankind. When such attitudes are projected onto children, the usual adult responses are either overidealization and overidentification of childhood, in which society is seen as an adversary, or stern warnings about the need for discipline, control, and moral rectitude, in which the child is seen as an adversary. Redl has used the "Sputnik neurosis" as an example of displacement onto children of concern about our own adequacy vis-à-vis the Russians (16). Other present-day examples in which children become the focus of adult conflicts are school busing (race) and school prayer (religion). The political football of busing in the election primaries of 1972 was a disgraceful example of adult value conflicts being displaced onto children, whose own feelings and reactions were almost totally ignored as the arguments grew louder and louder. The ambivalence described by Rexford is clearly in evidence at the two extreme ends of childhood—infancy and adolescence. The important experiences of infancy are being newly discovered and hotly contested. At the other extreme, adolescence provides a continuing focus of society's own disputes; it is the most recent part of childhood to be "identified" as a special one. Hence it is not surprising that social attitudes are still developing and that conflict over childhood remains the order of the day.

CONCLUSIONS

Despite this, a number of social and cultural currents that are completely unrelated to the problems of projection and ambivalence seem to represent gradual and significant progress toward a general acceptance of children's needs and rights. Although it is not yet possible to sort out their eventual significance, their potential is highly relevant to the continued development of child advocacy.

First, many feel we are in the process of an historical revolution equal to that of the 1500s and 1800s. The terms "post-industrial society," "technocratic revolution," "cybernetic revolution," "information explosion," "spaceship Earth," and many others help to characterize some of the emerging dimensions. Whatever else these terms contain, they imply profound changes in the relationships between a space-aged society and its youth, e.g., the generation gap. The extraordinary demands for adaptation in this period of swift change may soon require matching and supportive societal response toward youth. Besides these qualitative changes in society is the quantitative increase in the numbers of children and youth. Ambivalence and advocacy aside, it is difficult to imagine any nontotalitarian society continuing to ignore the legitimate needs of a group that comprises one-third of its whole! Finally, probably in response to the qualitative and quantitative changes in the state of children and youth in contemporary society, the age of political participation is being changed from 21 to 18 years; in a sense, children are no longer political nonentities. Although it may be argued that this is not a major change, it can also be argued that the late adolescent may vote as a newly arrived emigrant from childhood, with both empathy and advocacy for those who are still prepolitical.

In summary, any of these factors promises to support and extend the concept of child advocacy viewed in historical perspective. Our conclusion, then, is that child advocacy will become a meaningful addition to the store of social and scientific knowledge that becomes history. Although it has not yet been realized in practice, it seems to represent the recognition by society that the developmental needs of its children are of such importance that they must be ensured as rights to be promoted and protected by societal structures. In a sense, the advocacy of the 1970s expresses finally the recognition that the child is not a neurotic symbol or subject for the displacement or projection of adults' hopes and fears; he is neither the property of parents nor a creature of the state.

A Symposium: Should Homosexuality Be in the APA Nomenclature?

ROBERT J. STOLLER, M.D., JUDD MARMOR, M.D., IRVING BIEBER, M.D., RONALD GOLD, CHARLES W. SOCARIDES, M.D., RICHARD GREEN, M.D., AND ROBERT L. SPITZER, M.D.

A session of the annual meeting of the American Psychiatric Association in Honolulu, Hawaii, on May 9, 1973, was devoted to "Should Homosexuality Be in the APA Nomenclature?"[1]

The participants were:

Robert J. Stoller, M.D., Professor of Psychiatry, University of Southern California School of Medicine, Los Angeles.

Judd Marmor, M.D., Franz Alexander Professor of Psychiatry, University of Southern California School of Medicine, Los Angeles.

Irving Bieber, M.D., Clinical Professor of Psychiatry, New York Medical College, New York City.

Ronald Gold, Gay Activists Alliance, New York City.

Charles W. Socarides, M.D., Associate Professor of Psychiatry, Albert Einstein College of Medicine, New York City.

Richard Green, M.D., Associate Professor of Psychiatry in Residence, University of Southern California School of Medicine, Los Angeles.

Their papers are abstracted below. The session was organized and chaired by Robert L. Spitzer, M.D., Director, Evaluation Section, Biometrics Research, New York State Department of Mental Hygiene, 722 West 168 St., New York, N.Y. 10032, and Associate Professor of Clinical Psychiatry, Department of Psychiatry, Columbia University. His paper, which is also abstracted below, was written after the meeting. Reprint requests should be directed to Dr. Spitzer.

Criteria for Psychiatric Diagnosis

BY ROBERT J. STOLLER, M.D.

IS HOMOSEXUALITY a diagnosis? A diagnosis is supposed to be a highly compact explanation. To make a proper diagnosis in any branch of medicine there should be: a syndrome—a constellation of signs and symptoms shared by a group of people, visible to an observer; underlying dynamics (pathogenesis)—pathophysiology in the rest of medicine, neuropathophysiology or psychodynamics in psychiatry; and etiology—those factors from which the dynamics originate. When these exist, one can save time by using shorthand, knowing that a word or two—a label, a diagnosis—communicates to others what we know. Unfortunately, the conditions for which our specialty was developed do not usually fulfill these three criteria.

If one uses the above criteria for considering a condition a diagnosis, homosexuality is not a diagnosis because: 1) there is only a sexual preference (noticeable because it frightens many in our society), not a constellation of signs and symptoms; 2) different people with this sexual preference have different psychodynamics underlying their sexual behavior; and 3) quite different life experiences can cause these dynamics and behavior. There *is* homosexual behavior; it is varied. There is no such *thing* as homosexuality. In that sense it should be removed from the nomenclature.

As regards pathogenesis, probably no one these days, not even among those favoring the diagnosis, believes in a unitary cause for homosexual behavior; that would make it a *thing*. The fine reviews of the literature on etiology by Bieber and associates and Socarides, plus their own findings (1, 2), reinforce the impression that many paths lead to one's preferring members of his own sex. This is true even, and especially, with analytic theories of etiology.

Part of a Natural Realm

However, there is something disreputable in using our feeble method of diagnosis and psychiatrists en masse as the whipping boys for the cruel manner in which homosexuals have been and still are treated. These diagnostic issues are not the real source of homosexuals' mistreatment (although they can be borrowed for such use). At our best, we—since Freud's lead—are partly responsible for the fact that homosexuals can begin fighting back against society. Even though we are inaccurate when we call homosexuality a diagnosis, doing so has signified that the homosexual is part of a natural realm and not a member of the species of damned sinners. If homosexuals hate psychiatrists who would oppress them, let them also concede their debts to those who wish them free. If these niceties are bad for strategy, then let homosexuals—and other minorities—continue to flail us; the cause is honorable although the technique may be crude.

In the search for the multiple causes of homosexual behavior, I believe data can be found demonstrating that for many homosexuals the preferences in object choice and some essential, habitual nonerotic behavior (e.g., the effeminacy of some male homosexuals) were developed

[1] The APA Committee on Nomenclature and Statistics is currently considering this issue. Comments from readers on this question sent to the *Journal* will be forwarded to the committee before its January 1974 meeting.

as the result of trauma and frustration during identity development. Of course, these observations must be understood in the context that I believe they also hold true for most heterosexuals, although the traumas and frustrations are of different sorts and intensities.

Perhaps one can divide humans into two types, heterosexuals and others, as is the custom; if so, we might sort the two in the following idiosyncratic manner (rather as Freud did). I would consider the sexual styles of most humans, including most who prefer homosexual relations, as would-be heterosexual. (Analysts have also shown how heterosexuality may also contain homosexuality.) I believe that the sexual neuroses—the obvious perversions and even most variants of overt heterosexuality, e.g., compulsive promiscuity, use of pornography, preference for prostitutes, adult masturbation—are heterosexual distortions, compromises nonetheless filled with excitement, that allow one to give up certain desires if only others can be salvaged. If it will make the oppressed minorities more comfortable, we can all be given a diagnosis; such pronouncement would certainly not often distort the case. Everyone has his own style and distinctive fantasy content that he daydreams or stages with objects. Everyone is entitled to a category.

But why claim that heterosexuality is mankind's preference? The evidence for this as a biological given is certainly flimsy (although I would guess it is innate in some mild, reversible form). Yet I think that up to the present (not necessarily forever) heterosexuality has been the norm. It is the dominant presence in the ambiance of almost every human in infancy and childhood, because he is created in a family and families are palpably heterosexual (2, pp. 5–6). That sets the standard: heterosexuality is the product of the institution called the family. Then, too, even in childhood we know we are the result of an intimate, highly charged, astonishing, mysterious, unquestionably heterosexual act. So I see perversions (but not all sexual deviations and not all homosexual behaviors) as modifications one must invent in order to preserve some of one's heterosexuality. The form the perversion takes may be far from the extreme of a male preferring a female and vice versa, in which both wholeheartedly enjoy the sexual and loving aspects of their relationship. Yet, while unseen, that ideal may well be buried there in most of us, even if it is manifest in only a few.

A Holding Action

Until the day we know what we are doing, I suggest that—as a holding action—we try the following descriptive syndrome classification system:

A. The personality (character) type, habitual since childhood, e.g., obsessive-compulsive, schizophrenic, hysteric, depressive.
   1. The presenting syndrome, e.g., drug dependence, anxiety neurosis, schizophreniform psychosis.
      a. Subsidiary syndromes also present, e.g., alcoholism; nonpsychotic organic brain syndrome with senile brain disease; psychophysiologic respiratory disorder (asthma).

Sexual preference, e.g., heterosexual, monogamous, with accompanying fantasies of being raped by a stallion; homosexual, with foreskin fetishism; heterosexual, with preference for cadavers; homosexual, with disembodied penises (tearoom promiscuity); heterosexual, voyeurism; homosexual, expressed only in fantasies during intercourse with wife.

Only when diagnoses fail to describe succinctly and accurately should they be removed. Since that is the case for homosexuality, it cannot function as a true diagnosis; remove it. And since that is true for most of the rest of the "diagnoses" of psychiatry, let us scrap the system (although not yet all the labels) and start afresh.

Homosexuality and Cultural Value Systems

BY JUDD MARMOR, M.D.

PROPONENTS of the mental illness label for homosexuality base their arguments on three major themes: 1) that homosexuality is the consequence of "disordered sexual development," 2) that it is a deviation from the biological norm, and 3) that psychodynamic studies of homosexuals always reveal them to be deeply disturbed individuals.

The disordered sexual development theme is based on the finding that a certain type of disturbed parent-child relationship is a background factor in most cases. There seems to be an assumption in this theme that if there is a disturbed parent-child relationship in the background of someone with variant sexual behavior this proves that the disturbed relationship is causally responsible and that the individual with such variant behavior must be mentally ill.

There are a number of fallacies in this argument. First, we know that although most homosexuals show the "typical" family constellation, by no means do all of them. Secondly, not all people who do have such family constellations in their background become homosexual. Third (and most importantly) to call homosexuality the result of disturbed sexual development really says nothing other than that you disapprove of the outcome of that development. *All* personality idiosyncrasies are the result of background developmental differences, and *all* have specific historical antecedents. The concept of illness cannot be extrapolated on the basis of background but must rest on its own merits.

Deviant Behavior not Necessarily Psychopathology

It is my conviction that we do not have the right to label behavior that is deviant from that currently favored by the majority as evidence per se of psychopathology. And, as a matter of fact, we do *not* do so except where we are reflecting our culture's bias toward a particular kind of deviance. In a democratic society we recognize the rights of individuals to hold widely divergent religious or ideational preferences, as long as their holders do not attempt to force their beliefs on others who do not share them. Our attitudes toward divergent sexual preferences,

however, are quite different, obviously because moral values—couched in "medical" and "scientific" rationalizations—are involved.

There are some psychiatrists who would argue that individuals who adhere to unusual life-styles are indeed neurotic and that they suffer from various developmental fixations or arrests that account for their inability to adhere to the behavioral or ideational standards of the majority. Such labeling tends to define normality in terms of behavioral adjustment to cultural conventions rather than in terms of ego strengths and ego-adaptive capacities, and it puts psychiatry clearly in the role of an agent of cultural control rather than of a branch of the healing arts.

Moreover, the relativity of our contemporary sexual mores should not be ignored in any scientific approach to sexual behavior. In a cross-cultural study of 76 societies other than our own, Ford and Beach (3) found that in nearly two-thirds of them homosexual activities were considered normal and socially acceptable, at least for certain members of the community. Nor were all these societies necessarily "primitive" ones. In ancient Greece —a society that we admire and feel indebted to culturally, philosophically, and scientifically—overt homosexual relations between older men and youths was not only considered acceptable but was an institutionalized practice cultivated by heterosexual, healthy, honorable, normal men.

Bisexuality—Our Mammalian Inheritance

The second major argument for the illness viewpoint is that homosexuality, in contrast to other forms of behavioral deviance, is biologically unnatural. Dr. Frank Beach, the eminent biologist, has summarized the evidence on this by pointing out that bisexual behavior has been observed in more than a dozen mammalian species and "undoubtedly occurs in many others not yet studied." He concluded: "Human homosexuality reflects the essential bisexual character of our mammalian inheritance. The extreme modifiability of man's sex life makes possible the conversion of this essential bisexuality into a form of unisexuality with the result that a member of the same sex eventually becomes the only acceptable stimulus to arousal" (4).

Thus, from an objective biological viewpoint there is nothing "unnatural" about homosexual object choice. To illustrate how specious the argument is concerning the supposed biological unnaturalness of homosexuality let us consider some other conditions that are also outside of the presumably customary biological patterns. What about vegetarians? After all, most human beings are "naturally" meat-eaters, but we don't automatically label vegetarians as mentally ill. Or what about celibacy? Do we automatically assume that all people who choose a life of sexual abstinence are mentally ill simply because they do not follow the "natural" biological mating patterns? Obviously, we do not.

The third argument that is often advanced is that any careful study of the personality of homosexuals will show that they are really disturbed individuals. In contrast to Socarides, who holds the view that all homosexuals are practically borderline psychotics, Bieber concedes that many homosexuals can be well-adjusted individuals, but he argues that they still suffer from "pathology."

Happy, Constructive, and Realistic Homosexuals

What *does* constitute the intrinsic "pathology" of a socially well-adjusted homosexual? I submit that in the view of Bieber, Socarides, and others who share their viewpoint, it is primarily that his sexual preference differs from that of the majority of society. I do not deny that there are homosexuals who, just like heterosexuals, suffer from a wide variety of personality disorders and serious mental illnesses, although much of the dis-ease that they suffer from is not intrinsic to their homosexuality but is a consequence of the prejudice and discrimination that they encounter in our society.

But I believe there is now an incontrovertible body of evidence that there are homosexual individuals who, except for their variant object choice, are happy with their lives and have made a constructive and realistic adaptation to being members of a minority group in our society. I consider the kind of evidence that Socarides marshals from his clinical practice as essentially meaningless in this regard. As I have often pointed out, if our judgment about the mental health of heterosexuals were based only on those whom we see in our clinical practices we would have to conclude that all heterosexuals are also mentally ill.

The final absurdity of this is the impossibility of trying to define at what point a person becomes a homosexual who is labeled as having a mental disorder. Some defendants of the illness theory try to justify it by saying that it applies only to obligatory homosexuality. Does this mean that only type 6 homosexuals are mentally ill and all the others are not? Or that types 4, 5, and 6 are ill but not 1, 2, and 3? The whole process of such labeling is unpleasantly reminiscent of the Hitlerian process of trying to determine what fraction of black or Jewish ancestry a person might be permitted to have and still be considered an acceptable member of society with full legal rights.

Surely the time has come for psychiatry to give up the archaic practice of classifying the millions of men and women who accept or prefer homosexual object choices as being, by virtue of that fact alone, mentally ill. The fact that their alternative life-style happens to be out of favor with current cultural conventions must not be a basis in itself for a diagnosis of psychopathology. It is our task as psychiatrists to be healers of the distressed, not watchdogs of our social mores.

Homosexuality—An Adaptive Consequence of Disorder in Psychosexual Development

BY IRVING BIEBER, M.D.

THREE QUESTIONS seem most relevant to the question of

removing the term "homosexuality" from the *Diagnostic and Statistical Manual of Mental Disorders* or changing the current designation:

1. Is homosexuality a normal variant of sexual development and sexual functioning? The long-term study that my colleagues and I reported in 1962 (1), further investigations of colleagues, and the extensive clinical experience of myself and others since then leave no doubt that homosexuality is not merely a variation of normal adult sexuality. Observations on olfaction offer supporting evidence that humans born with normal gonads and genitals are biologically programmed for heterosexual development. From early life, olfaction plays a central role in sexual organization and functioning; it steers the infant toward heterosexual objects and works as an important triggering mechanism in sexual arousal (5, 6). Homosexuality does not occur without antecedent heterosexual development; it appears only *after* sexual responsivity to heterosexual objects has been established. Psychoanalytic evidence of heterosexual responses in homosexuals can almost always be demonstrated.

I have repeatedly emphasized that the dislocations in heterosexual organization of biologically normal children occur as a consequence of pathological family contexts—more specifically, pathologic relationships between parents and child. Typically, mothers of homosexuals are inappropriately close, binding, often seductive, and tend to inhibit boyish aggressiveness. The fathers are overtly or covertly hostile; this is expressed in detachment, streaks of cruelty, or frank brutality. The relationship between the parents is generally poor; often the husband is held in contempt by a wife who prefers her son. The prehomosexual child may be exposed to rejection and hostility from other significant males, such as brothers and peer mates. Defective masculine relationships deprive such a boy of needed masculine figures for identification and modeling that are ultimately sought, in part, in homosexuality. It then becomes a substitutive adaptation, replacing the heterosexuality that is made inadequate or unavailable by a network of induced fears about heterosexual behavior. Within a substitutive adaptation, attempts are made to acquire missing sexual and romantic gratification. Through various homosexual maneuvers and activities, reparative attempts are made to strengthen masculine self-esteem and to alleviate profound feelings of rejection from men. Through homosexuality, reassurance and acceptance are sought from other men. Contrary to popular notions, homosexuality is not an adaptation of choice; it is brought about by fears that inhibit satisfactory heterosexual functioning.

Inherent Psychological Pain

The gay activists and their proponents among some psychiatrists claim that many men are neurotic about their homosexuality only because society is prejudiced. Extinct cultures, such as the ancient Greek, are held up as prejudice-free examples, while cultures and present-day societies where there is no homosexuality are disregarded. The animal evidence has rested heavily on statements by Frank Beach. His position on animal homosexuality has changed, however, and in 1971 he wrote, "I don't know any authenticated instances of males or females in the animal world preferring a homosexual partner, if by homosexuality you mean complete sexual relationships including climax.... It's questionable that mounting in itself can be properly called sexual" (7).

Opponents of my views have accused me and other colleagues with similar ideas of being prejudiced, reactionary, and homophobic. The trouble with such ad hominem attacks is that they do not get to the heart of the matter but serve merely as diversionary methods to discredit without risking an objective engagement with the evidence. As I see it, society at large does not produce a homosexual condition nor can it mitigate the inherent psychological pain. If all discrimination against homosexuals ceased immediately, as indeed it should, I do not think their anxieties, conflicts, loneliness, and frequent depressions would be short-circuited.

2. If homosexuality is not normal, how should it be categorized? In the past century, psychiatry and the allied behavioral sciences have amassed an enormous body of data, although psychiatric diagnostic classification is the weakest part of this extraordinary development. Our present nosology is based on very different categories of criteria. The diagnoses of mania and depression are based on the salient symptom; of schizophrenia, on a constellation or cluster of signs and symptoms; of personality disorders, on psychodynamic formulations; and of sociopathy, on sociologic criteria. Classification of homosexuality has reflected this medley of psychiatric criteria. It is often referred to as "sexual deviation." Literally, deviation is a statistical term denoting movement away from a median or statistical norm. Deviation and pathology are not necessarily related; genius is as deviant as is mental deficiency. In my opinion, the term "sexual deviation" is ambiguous, vague, and not useful as a diagnosis or as a nosologic category.

Homosexuality: Sexual Inadequacy

Masters and Johnson (8) used criteria that qualified as functional and dysfunctional to classify sexual disorders, and they introduced the term "sexual inadequacy." Under this rubric, they included frigidity and sexual impotence. The psychodynamic common denominator of frigidity, impotence, premature ejaculation, and homosexuality consists of a network of fears about being effective in heterosexual activity. I suggest that homosexuality be characterized as a type of sexual inadequacy since most homosexuals (especially those who are exclusively homosexual) cannot function heterosexually.

I think, too, that adaptational concepts are very useful in formulating broader diagnostic contexts. Homosexuality could be classified as an adaptation to inhibited, dislocated heterosexual functioning; this would leave room for an expanded description of the patient's heterosexual difficulties.

3. Does the inclusion of homosexuality in the diagnostic manual make homosexuals "sick," as they claim? Discrimination against homosexuals existed long before modern psychiatric and diagnostic manuals. Psychiatry

particularly psychoanalysis, has contributed significantly toward altering archaic, moralistic, and pseudoscientific concepts. Freud (9) was the first to discard the notion that homosexuality was a degenerative disease. He classified it as a disorder of psychosexual development rather than as sinful and antisocial.

There is no reason to believe that if homosexuality were removed from the diagnostic manual there would be a significant alteration in existing social attitudes. Even if it could be shown that improved social attitudes would eventuate, this would not be reason enough to exclude the term if we agree that homosexuality is not normal and is a treatable condition.

Removal of the term from the manual would be tantamount to an official declaration by APA that homosexuality is normal. Undoubtedly it would be interpreted that way. More importantly, dropping the term would be a serious scientific error. Such an action would also interfere with effective prophylaxis. Prehomosexual boys are easily identifiable and should be treated. Further, young men in conflict about their sexual direction may be discouraged from seeking treatment by those who would reassure them that their homosexual proclivities are normal and that it is only "society," with its outmoded value system, that makes them reject a homosexual preference.

Stop It, You're Making Me Sick!

BY RONALD GOLD

I HAVE come to an unshakable conclusion: the illness theory of homosexuality is a pack of lies, concocted out of the myths of a patriarchal society for a political purpose. Psychiatry—dedicated to making sick people well—has been the cornerstone of a system of oppression that makes gay people sick.

To be viewed as psychologically disturbed in our society is to be thought of and treated as a second-class citizen; being a second-class citizen is not good for mental health. But that isn't the worst thing about a psychiatric diagnosis. The worst thing is that gay people believe it.

Nothing is more likely to create neurotic anxiety than "a lack of feeling of wholeness," and nothing is more likely to alienate you from a major aspect of yourself than to be told incessantly that it's sick.

At 14 years of age I discovered what the "experts" said about the way I love: "infantile sex," "inevitable emotional bankruptcy," "a masquerade of life filled with destruction and self-deceit." So I went to my older sister and she sent me to a psychiatrist. He shot me full of sodium pentothal and scared me out of my wits. It is amazing how I could have kept on believing this nonsense about homosexuality when so little of it had anything to do with my life. But I went willingly to other psychiatrists and learned from them that a part of me I didn't want to give up needed to be excised. I was ready for "psychic annihilation"; I became a heroin addict. This time I was sent to the Menninger Clinic, and there I was convinced that my "cure" must include a change in sexual orientation. So when it was agreed that I was through with treatment, it seemed to me I'd done only half a job. But I soon found that all I needed for another person to love me was to like myself better. I met a young man, and we had a good, happy life for 12 years. When we broke up, our conflicts weren't out of the psychiatric literature. They were just like the tales of heterosexual divorce you read about in *Redbook*.

The man I live with now is a warm, loving, open person. For the past two years we've been going through the joyful process of discovering the full repertory of mutuality—easier for two members of the same sex.

Psychological Growth Through Resisting Oppression

There are advantages to being gay. I learned that in the gay movement. And I learned something else: that I was oppressed and must make the choice to do everything I can to cease being an accomplice in my own oppression. I've had an immense sense of psychological growth through this decision. I've fought through to a sense of myself as a whole person—a good, concerned, loving, fighting-mad homosexual. I'm fighting the psychiatric profession now, but I know that a false adversary situation has been drawn between psychiatry and Gay Liberation. We can save you the trouble of treating some people, and we can be a helpful adjunct for many of your patients by pointing them along the road to self-esteem.

After our meeting with your Committee on Nomenclature and Statistics, its chairman said that "whether a person prefers to have sexual relations with a member of the same or of the opposite sex is in itself not an indicator of mental disorder." But, he added, "What are we to do about the homosexual who comes to us and says he's miserable, that he wants to change?" Such people do need help. But is it their homosexuality that's doing them in? Or is it something that psychiatry has helped to create: irrational fear and hatred of homosexuality? Instead of acceding to requests for brainwashing, what you can help these people realize is that there are many successful, well-adjusted people in various professions (including psychiatry) who are homosexual. You can help them to see that successful sexual adjustment of any kind cannot be achieved in a climate of guilt and fear.

When these patients see themselves as people, not sets of stereotypical patterns, I suspect that most of them (about as many as you get with your current techniques) will go on being gay. Only they'll be happy about it. Perhaps the same percentage you have now will wind up predominantly heterosexual. And many of those who had been exclusively homosexual—many more than you now count as treatment "successes"—will discover a heterosexual component in themselves. We have found that such things happen frequently in the Gay Liberation movement.

I feel better since I've joined Gay Liberation. I work better, I'm happier in love. Would you rather have me the way I am? Or would you suggest another round of therapy? I think you really know that I'm not sick now, that my homosexuality is simply a part of me that in the past I wasn't allowed to accept. And I think you're prepared to

agree that my previous illness was at least in part a direct result of the crimes perpetrated on me by a hostile society. You have been willing accomplices in such crimes. It is now time for you to prevent them. Take the damning label of sickness away from us. Take us out of your nomenclature. Work for repeal of sodomy laws, for civil-rights protections for gay people.

Most important of all, speak out. You've allowed a handful of homophobes to tell the public what you think. It's up to you now to get on the talk shows and write for the weeklies, as they do. You've got to tell the world what you believe—that Gay is Good.

Homosexuality: Findings Derived from 15 Years of Clinical Research

BY CHARLES W. SOCARIDES, M.D.

> I've got to get this homosexual monkey off my back. I just frankly can't live with it. I must either extinguish it, if I can, or maybe by religion extinguish all sex. And the other thing is to be dead. To have anonymous sex with other sick men, I can't make a life out of that. The homosexuals I know think I'm copping out, and if it's not hereditary they feel at least that it's impossible to change. They say to me, "Once homosexuality is established you can't get out or if you do try to get out you'll go nuts." They tell you that you will be isolated and they keep telling you you're a traitor trying to leave the group, turning against your own kind, that you're trying to do something and be something that you're not. They say you're self-indulgent and selfish, feeding your ego in a very selfish kind of way in that you're enjoying your neurosis in trying to get well.

THAT QUOTATION from a patient is why some of us treat homosexuals: because people come to us voluntarily and seek our help. They are in agony over their condition.

The Task Force on Homosexuality appointed by the New York County District Branch of the American Psychiatric Association, of which I was the chairman, unanimously agreed in April 1972 that homosexuality arises experientially from a faulty family constellation. (Some few homosexuals come from an institutional background, but in our opinion they present special problems.) It was our finding that homosexuality represents a disorder of sexual development and does not fall within the range of normal sexual behavior. Further, between one-third and one-half of male homosexuals who seek treatment, including those who had formerly been exclusively homosexual, become exclusively heterosexual as a result of psychoanalytically oriented psychotherapy.

The most extensive comparison study oriented to establishing the etiology of male homosexuality was published in 1962 (1). It is a report on 106 male homosexuals and 100 male heterosexuals, distributed in psychoanalytic treatment with 77 members of the Society of Medical Psychoanalysts.

This study established a continuity and severity of pathological parent-child relationships in the background of all the homosexuals studied to an extent not found in the comparison group. The frequency of a parental combination consisting of a close-binding, overintimate mother and a hostile, detached father statistically differentiated the homosexuals from the heterosexual group at the .01 level of confidence.

The majority of mothers of homosexuals interfered with the development of their sons' peer group relationships, heterosexual development, assertiveness, and decision making; the fathers were demasculinizing. One conclusion of this study was that the son who becomes homosexual is the focal point of this intrafamilial pathology.

Preoedipal Theory of Causation

In 1968 (2), after 15 years of clinical research, I introduced the concept that in all homosexuals there has been an inability to make the progression from the mother-child unity of earliest infancy to individuation. This was called the preoedipal theory of causation. This failure in sexual identity, normally achieved by the age of three, is due to a pathological family constellation in which there is a domineering, psychologically crushing mother who will not allow the child to attain autonomy from her and an absent, weak, or rejecting father who is unable to aid the son to overcome the block in maturation. As a result there exists in (obligatory) homosexuals a partial fixation with the concomitant tendency to regression to the earliest mother-child relationship.

It is my conviction that it is necessary for all human beings to complete the separation-individuation of early childhood (10) in order to establish gender identity. Failure to do so results in a deficit in masculinity for boys, with a corresponding intensification and continuation of the primary feminine identification with the mother; thus begins the course toward homosexual development. It may well be clear now why homosexuality is prevalent, has existed since the beginning of recorded history, and spans all sociocultural levels.

While there was total agreement among members of the task force that the parents, consciously or otherwise, are the primary architects of the homosexual psychic organization, some placed major emphasis on the mother's influence in the preoedipal period, while others stressed the inordinate fears of male aggression coupled with a yearning for male acceptance and affection stemming from the deleterious parental attitudes and behavior. Those who subscribe to preoedipal origin emphasize primitive fears of injury by women.

A sound scientific basis for deciding whether the homosexual suffers from a psychosexual disorder has been handicapped by reports of psychological testing that were offered as proof that there are no discernible differences between homosexuals and heterosexuals insofar as such protocols are concerned (11, 12). Having reviewed these data in detail, we strongly recommend that these tests, dating back to 1957 and 1958, be repeated by other investigators with a much more rigorous methodology than was originally used.

Not a "Sexual Dysfunction"

Scientific knowledge is also damaged when attempts are made to classify homosexuality simply as "sexual dysfunction," a term regularly applied to loss of erection, premature ejaculation, retarded ejaculation, or total impotence. These impairments constitute disturbances of the standard male-female pattern. It is characteristic of the standard or normal sex experience that it take place between a male and a female. It is also characteristic that orgasm produced by intravaginal penetration is fully within the capability of the male partner, and that this coital activity has the potentiality for reproduction. These criteria are basic to elementary human biology and are not subject to change by social or political movements. Individuals unable to achieve sexual release within this standard pattern, with all its possible variations of foreplay, etc. (of which there are an infinite number), turn to modified patterns for orgastic relief, and these constitute sexual deviations. Thus the immutable distinctions between sexual deviations and sexual dysfunctions cannot be semantically blurred without incurring formidable scientific chaos.

As to the contention that in homosexuality there are no clinical symptoms, no course of development, and no treatment, we strongly disagree. There are symptoms and there is a course and there is a treatment—often a very effective treatment. The limitations of space do not allow me to comment on these here beyond observing that in addition to the uncovering techniques of depth therapy, treatment requires educational and retraining measures, interventions, and modifications in the handling of transference, resistance, and regression.

Let us bear in mind that psychiatrists have been in the forefront in helping homosexuals. It was Freud who opened the gates of freedom and humanity to the homosexual. And it was others after him—investigators who dared, who were not afraid of homosexuals, who had no "homophobia" of which we are accused—who could therefore treat homosexuals who want to be treated. I urge that all persecutory laws against the homosexual be abolished at once. It is unthinkable that homosexuals be persecuted for something over which they have no choice. Such laws are a direct contradiction to psychiatric as well as humane values.

Should Heterosexuality Be in the APA Nomenclature?

BY RICHARD GREEN, M.D.

FOUR MAJOR CRITERIA are typically called upon to classify behavior as emotionally disordered. First is gross social dysfunction. Here an individual's behavior is such that to any but the most cynical of observers there is objective evidence that the individual is dysfunctional. The mental functioning of the regressed schizophrenic, the manic, the profoundly depressed, the severely retarded, and the patient with chronic brain syndrome precludes effective social survival.

Second, there exist the less socially obvious emotional limitations. Here inner discord that reduces the efficiency of behavioral functioning is experienced by the individual. Examples include severe anxiety and phobias of various types. Classification of the latter, however, becomes problematic when one considers the relative social consequences of snake phobia, germ phobia, and agoraphobia.

The third criterion of diagnosis is somewhat softer science. This focuses on culturally variant behavior. Using statistical deviance per se as a diagnostic basis evokes problems. Geniuses are deviant. So are the left-handed, vegetarians, pacifists, the celibate, and the esoterically religious. The relationship of idiosyncratic and delusional thinking to cultural accommodation comes into focus when one considers the different view of a religion adhered to by one person, a thousand, or a million. Then too there is the sociopath. His behavior is also deviant and, further, may result in undesirable effects on society. This person may feel no anxiety and not appear grossly dysfunctional. However, his behavior is at odds with external societal values and is labeled as an emotional disorder.

Next, there is a criterion that is scientifically the softest yet. Behavior is judged to be sick or healthy, ordered or disordered, based on a theoretical model of human psychological development. A theory may define specific behavioral phenomena as evidence of disorder. In this regard, classic psychoanalytic theory deems homosexual object choice as psychological immaturity, an arrest of psychosexual development. Castration fear and penis envy are universally posited developmental facts, and resolution of the oedipal crisis is the developmental rite of passage to mature sexuality. The scientific merits of psychoanalytic theory have been debated at length (13).

Heterosexuality as a Disorder

The title of this paper asks the question whether heterosexuality should be in the APA nomenclature. There are in fact some places where heterosexuality and its derivatives are cited. These include pedophilia (presumably this includes children of the opposite sex), exhibitionism (typically the object is a person of the opposite sex), voyeurism (same as the preceding), sadism and masochism (if it is with a partner of the opposite sex), and transvestism (most transvestites are heterosexual).

One additional diagnostic term in our current nomenclature can refer to heterosexuality. This term is under the heading of psychophysiologic genitourinary disorder. Here psychogenic dyspareunia and impotence can be cited, and presumably also nonorgasmia in the female and premature ejaculation in the male.

Are there other places where heterosexual behavior might be considered worthy of diagnosis and classification? Styles of heterosexual conduct do indeed form much of what is dealt with by psychiatrists. Instability in maintaining a love relationship and neurotic uses of sexuality—in which sexuality is used to control others,

as a substitute for other feelings of self-worth, or as a defense against anxiety and depression—constitute a significant bulk of the disorders treated in outpatient psychiatry. Yet there is no specific mention of such ego-dystonic, neurotic uses of heterosexuality in the nomenclature. By contrast, the homosexual is considered to be manifesting a disorder, whether or not he or she is able to maintain a stable interpersonal relationship, feels comfortable about his or her sexuality, and does not utilize it in a self-destructive manner.

Homosexuality as a Disorder

Where in the above gross criteria of mental disorder, other than as a derivative of a theoretical model of personality development, do we place homosexual behavior when it is engaged in by two consenting adults in private? In terms of gross psychologic social functioning the homosexual typically appears no different from his heterosexual counterpart. He or she may hold a responsible occupational and social position. Psychiatrists, other physicians, lawyers, ministers, politicians, authors, etc., may be homosexual. Clearly there is no gross impairment of the kind seen in acute schizophrenia, mania, or organic brain syndromes. With respect to intrapsychic adjustment, the studies that have used comparable samples of nonpatient heterosexual and homosexual subjects typically find no significant differences between the groups on such factors as anxiety and depression (14). With respect to civil issues, homosexual conduct between consenting adults is not illegal in most western European countries, Canada, and some of the United States.

A Proposed New Classification

Can we attain a compatible coalition between those who consider homosexuality a profound mental disorder and those who view it as an alternate life-style beyond the legitimate purview of the medical profession?

The past few years have witnessed an explosion in the research and treatment of various aspects of sexual behavior. Due to the work of Masters and Johnson, considerable professional attention is now being paid to the problems of sexual dysfunction, particularly impotence and premature ejaculation in the male and nonorgasmia in the female. Sexual dysfunction is externally maladaptive and is accompanied by anxiety, depression, and other inner distress.

The more traditional model of emotional disorder considers sexual relationships as dynamic interpersonal phenomena within the scope of ego functioning. Again, compatibility between the phenomena of the homosexually oriented and the heterosexually oriented can be attained. The classification I am proposing here would include the heterosexual or the homosexual who finds it difficult to maintain desired object relationships, who compulsively uses sexuality to ward off anxiety or depression, or whose sexuality typically leads to depression or anxiety. Within this same general category would also be classed those persons who request reorientation or modification of sexual object preference.

The following classification is proposed:

Sexual dysfunction I. This term is applied when physiological dysfunction of psychogenic origin is the primary presenting symptom.

A) Male impotence: 1) with same-sexed partner, 2) with other-sexed partner; B) male premature ejaculation: 1) with partner of same sex, 2) with partner of opposite sex; C) female nonorgasmia: 1) with partner of same sex, 2) with partner of opposite sex.

Sexual dysfunction II. This term is applied when psychogenic distress is the primary presenting symptom. Physiologic dysfunction may or may not be an accompanying factor.

A) Anxiety, depression, and other neurotic reactions secondary to interpersonal aspects of sexuality, not primarily related to physiologic dysfunction: 1) with partner of same sex, 2) with partner of opposite sex; B) dissatisfaction with sexual orientation: 1) dissatisfaction with exclusive or primary homosexual orientation, 2) dissatisfaction with exclusive or primary heterosexual orientation.

The nomenclature would retain exhibitionism, voyeurism, sadism, masochism, pedophilia (and *add* rapism) when such behavior is of a repetitive nature.

With this new classification, psychiatry would have an objective basis for categorizing sexuality that is free of cultural bias, not based on partially accepted theoretic models, not based on the judgment of an external professional agent, but, rather, is patient-activated. Further, it would not stigmatize the individual and would not reinforce legal, religious, and other forms of social discrimination that are a product of the current classification.

A Proposal About Homosexuality and the APA Nomenclature: Homosexuality as an Irregular Form of Sexual Behavior and Sexual Orientation Disturbance as a Psychiatric Disorder

BY ROBERT L. SPITZER, M.D.

CONTROVERSY RAGES as to whether homosexuality should be regarded as a pathological deviation of normal sexual development or as a normal variant of the human potential for sexual response. Recently this controversy has focused on the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders,* second edition *(DSM-II),* in which homosexuality is listed as an official diagnosis in the section on sexual deviations.

The proponents of the view that homosexuality is a normal variant of human sexuality argue for the elimination of any reference to homosexuality in a manual of psychiatric disorders because it is scientifically incorrect, encourages an adversary relationship between psychiatry and the homosexual community, and is misused by some people outside of our profession who wish to deny civil

rights to homosexuals. Those who argue that homosexuality is a pathological disturbance in sexual development assert that to remove homosexuality from the nomenclature would be to give official sanction to this form of deviant sexual development, would be a cowardly act of succumbing to the pressure of a small but vocal band of activist homosexuals who defensively attempt to prove that they are not sick, and would tend to discourage homosexuals from seeking much-needed treatment.

When all of the arguments are carefully examined, a few simple statements can be made with which hardly any major psychiatric opinion would disagree.

1. "Homosexuality" refers to an interest in sexual relations or contact with members of the same sex. Some experts in our field believe that predominant or exclusive homosexuality is pathological; other experts believe it is a normal variant.

2. A significant proportion of homosexuals are apparently satisfied with their sexual orientation, show no significant signs of manifest psychopathology (other than their homosexuality, if this is considered by itself psychopathology), and are able to function quite effectively. These individuals may never come for treatment, or they may be seen by a psychiatrist because of external pressure (e.g., court referral, family insistence) or because of other problems requiring psychiatric help (e.g., depression, alcoholism).

3. A significant proportion of homosexuals are quite bothered by, in conflict with, or wish to change their sexual orientation. There is debate within our profession as to why this is so. Some argue that it is an inevitable result of the underlying conflicts that cause homosexual behavior in the first place, while others argue that it is derived from a host of social and cultural pressures that have been internalized. Nonetheless, some of these individuals come voluntarily for treatment, either to be able to accept their sexual feelings toward members of the same sex or to increase their capacity for sexual arousal by members of the opposite sex.

4. Modern methods of treatment enable a significant proportion of homosexuals who wish to change their sexual orientation to do so. The exact percentage is controversial and not at all clear. At the same time, homosexuals who are bothered by or in conflict with their sexual feelings but who are either uninterested in changing or unable to change their sexual orientation can be helped to accept themselves as they are and to rid themselves of self-hatred.

What Is a Manual of Mental Disorders?

Decisions about the labeling problem in *DSM-II* require an understanding of the function of a manual of mental disorders. Its purpose, as its name clearly implies, is to list and define mental (psychiatric) disorders. Its purpose is not to list and describe all of the forms of human psychological functioning that are judged by the profession or some members of the profession as less than optimal, nor is its purpose to imply certainty about the nature of conditions when there is not a consensus in the profession.

For a mental or psychiatric condition to be considered a psychiatric disorder, it must either regularly cause subjective distress or regularly be associated with some generalized impairment in social effectiveness or functioning. With the exception of homosexuality (and perhaps some of the other sexual deviations when they occur in a mild form, such as voyeurism), all of the mental disorders in *DSM-II* fulfill either of these two criteria. (While one may argue that the personality disorders are an exception, on reflection it is clear that it is inappropriate to make a diagnosis of a personality *disorder* merely because of the presence of certain typical personality traits that cause no subjective distress or impairment in social functioning.) Clearly homosexuality per se does not meet the requirements for a psychiatric disorder since, as noted above, many homosexuals are quite satisfied with their sexual orientation and demonstrate no generalized impairment in social effectiveness or functioning.

The only way that homosexuality could therefore be considered a psychiatric disorder would be the criterion of failure to function heterosexually, which is considered optimal in our society and by many members of our profession. However, if failure to function optimally in some important area of life, as judged by either society or the profession, is sufficient to indicate the presence of a psychiatric disorder, then we will have to add to our nomenclature the following conditions: celibacy (failure to function optimally sexually), revolutionary behavior (irrational defiance of social norms), religious fanaticism (dogmatic and rigid adherence to religious doctrine), racism (irrational hatred of certain groups), vegetarianism (unnatural avoidance of carnivorous behavior), and male chauvinism (irrational belief in the inferiority of women).

If homosexuality per se does not meet the criteria for a psychiatric disorder, what is it? Descriptively, it is an irregular form of sexual behavior. Our profession need not now agree on its origin, significance, and value for human happiness when we acknowledge that by itself it does not meet the requirements for a psychiatric disorder.

Sexual Orientation Disturbance

Having suggested that homosexuality per se is not a psychiatric disorder, what about those homosexuals who are troubled by or dissatisfied with their homosexual feelings or behavior? These people have a psychiatric condition by the criterion of subjective distress, whether or not they seek professional help. It is proposed that this condition be given a new diagnostic category, which will replace the current undefined category of homosexuality in subsequent printings of *DSM*, defined as follows: "Sexual orientation disturbance. This is for people whose sexual interests are directed primarily toward people of the same sex and who are bothered by, in conflict with, or wish to change their sexual orientation. This diagnostic category is distinguished from homosexuality, which by itself does not constitute a psychiatric disorder. Homosexuality per se is a form of irregular sexual behavior and, with other forms of irregular sexual behavior that are not by themselves psychiatric disorders, are not listed in this nomenclature."

What will be the effect of carrying out such a proposal? Homosexual activist groups will no doubt claim that psychiatry has at last recognized that homosexuality is as "normal" as heterosexuality. They will be wrong. In removing homosexuality per se from the nomenclature we are only recognizing that by itself homosexuality does not meet the criteria for being considered a psychiatric disorder. We will in no way be aligning ourselves with any particular viewpoint regarding the etiology or desirability of homosexual behavior.

By creating a new category, "sexual orientation disturbance," we will be applying a label only to those homosexuals who are in some way bothered by their sexual orientation, some of whom may come to us for help. We will no longer insist on a label of sickness for individuals who insist that they are well and who demonstrate no generalized impairment in social effectiveness. We will thus help to answer the charge of some members of our own profession who claim that mental illness is a myth and that by labeling individuals with psychiatric diagnoses we are merely acting as agents of social control. Furthermore, we will be removing one of the justifications for the denial of civil rights to individuals whose only crime is that their sexual orientation is to members of the same sex. In the past, homosexuals have been denied civil rights in many areas of life on the ground that because they suffer from a "mental illness" the burden of proof is on them to demonstrate their competence, reliability, or mental stability. (By linking the removal of homosexuality from the diagnostic nomenclature with an affirmation of the civil rights of homosexuals, no implication is intended justifying the irrational denial of civil rights to individuals who do suffer from true psychiatric disorders.)

This revision in the nomenclature provides the possibility of finding a homosexual to be free of psychiatric disorder, and provides a means to diagnose a mental disorder whose central feature is conflict about homosexual behavior. Therefore, this change should in no way interfere with or embarrass the dedicated psychiatrists and psychoanalysts who have devoted themselves to understanding and treating those homosexuals who have been unhappy with their lot. They, and others in our field, will continue to try to help homosexuals who suffer from what we can now refer to as "sexual orientation disturbance," helping the patient accept or live with his current sexual orientation, or, if he desires, helping him to change it.

Oral Contraceptives, Pyridoxine, and Depression

BY FRANK WINSTON, M.B.B.S.

Taking steroid hormones for the control of ovulation may be associated with depressive mood changes in women who are predisposed to depression. The author postulates that such depression may in some cases be due to inhibition of the synthesis of biogenic amines in the central nervous system as the result of a functional pyridoxine deficiency caused by the estrogen in the oral contraceptives. It is suggested that this depression might be prevented or alleviated by the administration of supplementary vitamin B_6.

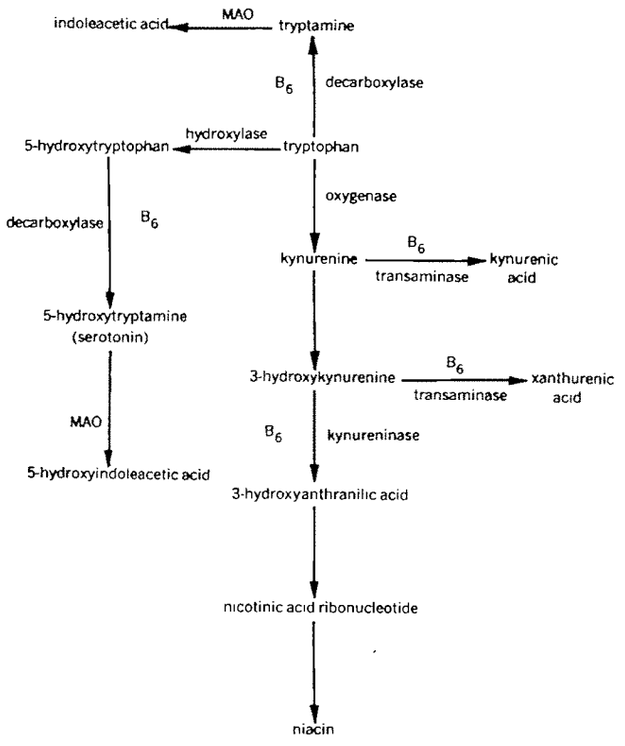
INVESTIGATIONS INTO THE EFFECT of oral contraceptives on mood have shown that, while their use may often alleviate premenstrual depression (1–3), a certain number of women will become seriously depressed with continued use (4–12) and that women who have a history of depressive disorder, severe premenstrual weepiness, or depression during pregnancy are those most likely to develop depression when they use oral contraceptives (5, 10, 12). Kutner and Brown (13) have questioned this latter finding.

Herzberg and Coppen (2) found that, although the use of oral contraceptives significantly improved premenstrual depressive symptoms in many of a group of 136 women, nine women stopped taking oral contraceptives because they developed depression and irritability. In a subsequent investigation Herzberg and colleagues (11) found that 6.6 percent of oral contraceptive users were more severely depressed than any member of the control group, but that there was no significant difference between the mean depression scores of the oral contraceptive users and the control group. In a highly critical review of the evidence associating depression with the use of oral contraceptives, Goldzieher and associates (14) found no significant difference in the incidence of nervousness and depression in oral contraceptive users and controls (severity of depression was not measured) and concluded that "the majority of nervousness, depression, and weight gain noted in oral contraceptive users is either coincidental or associated with the psychological impact of taking these agents rather than with any pharmacological effect." Similarly, Leeton and associates (15), in a placebo-controlled study that was based on one menstrual cycle, found no statistical difference between depression scores of oral contraceptive users and those of controls, but suggested that "positive effects on mood may have eliminated negative effects." A further study by Herzberg and colleagues (12) found evidence to support this suggestion, since women who had used the same oral contraceptive for a year had significantly lower mean depression scores than women who had stopped or changed their contraceptive during the same period.

While many investigators concur that depression may be a side effect of the use of oral contraceptives, the cause remains obscure. It has been suggested that depression occurring during oral contraceptive use is a psychological phenomenon (16). Although psychological factors no doubt play a part, the role of hormonal changes induced by oral contraceptives cannot be ignored, particularly since there is a known correlation of psychiatric disorder with the changing hormone levels of the menstrual cycle (17–19).

It has been reported that the more strongly progestogenic contraceptives, which are associated with higher monoamine oxidase (MAO) activity in the endometrium, cause a greater degree of depression (9); this finding led to the suggestion that the depression is related to an increase in brain MAO activity induced by the progestogen (9). Other investigators have failed to confirm this finding (3, 11, 20). In one study (3), statistical evidence was found that contraceptives containing higher doses of progestogen were associated with less severe depression.

There is no evidence that progestogen increases brain MAO. On the contrary, experiments with rats have shown that the injection of progesterone, although it increased endometrial MAO was without effect on other tissues, including brain tissue (21). Further, the amine changes found in rat brain after acute injection with progesterone did not indicate that they were caused by any generalized increase in MAO activity (22). For example, although the level of norepinephrine was lower than normal in the midbrain, it was markedly higher in the cortex and the concentration of 5-hydroxytryptamine (serotonin) was higher in all areas. Herzberg and associates (12) concluded that the susceptibility of the individual woman to developing symptoms is probably of greater importance than the composition of the oral contraceptive. Some possible factors that might determine such individual susceptibility are discussed below.



EVIDENCE

According to the biogenic amine hypothesis, the con-

Dr. Winston is in private practice at 313 Price Pl., Madison, Wis. 53705.

The author wishes to thank Dr. Raymond R. Brown, Professor of Clinical Oncology, University of Wisconsin School of Medicine, for his advice and encouragement.

FIGURE 1
*Modified Outline of Tryptophan Metabolism**

*"B_6" indicates that the reaction is dependent on the presence of pyridoxal phosphate.

trol of mood is related in some way to the concentrations in the central nervous system (CNS) of the biogenic amines, particularly serotonin (23, 24), tryptamine (25), and norepinephrine (26). The ratio of the concentrations of these amines is probably more important than the absolute levels of any one of them (27, 28). The concentrations of these amines are regulated by the activity of mitochondrial MAO, their synthesis from dietary amino acids, and other adaptive mechanisms. The evidence is very strong that there is a disturbance of tryptophan metabolism (figure 1) underlying the genesis of affective disorder. Both depressed and manic patients have been shown to have lower levels of 5-hydroxyindoleacetic acid (5-HIAA) in the cerebrospinal fluid than controls, an abnormality that persists after clinical recovery (28). Similarly, patients suffering from endogenous depression excreted significantly higher amounts of kynurenine in the urine than controls, an abnormality that also sometimes continued after recovery (29).

Women taking oral contraceptives show a marked disturbance of tryptophan metabolism along the kynurenine-niacin pathway, with abnormally high urinary excretion of several metabolites, particularly xanthurenic acid and, to a lesser extent, hydroxykynurenine and kynurenine, after receiving a loading dose of tryptophan (30–35). This metabolic disturbance is completely corrected by the administration of a large daily supplement of pyridoxine. A similar disturbance occurs during pregnancy (36, 37) and after the ingestion of cortisone (38). Progestogen given alone does not cause this disturbance (34, 35), so it can be taken to be an estrogenic effect, particularly since estrogen given alone causes the same disturbance (35, 39). Similar disturbances occur transiently during the normal menstrual cycle at the time of ovulation (40, 41) and just before menstruation (41), when estrogen levels are at their highest.

The exact cause of this disturbance has not been defined, but it is thought to be due either to 1) an increase in the formation of kynurenine by the induction of tryptophan oxygenase in the liver, as a result of the increased concentration of plasma cortisol that was induced by the estrogen (42), or 2) interference with certain vitamin B_6-dependent enzyme systems caused by the competition of estrogen conjugates with pyridoxal phosphate for binding sites on the apoenzyme (43). Both mechanisms of course may play a part, but it is clear that estrogen does not act simply by the induction of cortisol since subjects receiving cortisol have been shown to excrete about twice as much xanthurenic acid as controls after a 5 gm. loading dose of tryptophan (38), whereas women taking oral contraceptives excreted an average of 23 times as much xanthurenic acid as controls after a 2 gm. dose of tryptophan (31). This abnormality persists as long as the contraceptives are taken (44) and becomes more marked with time (34), a factor that may be of some importance in evaluating the results of studies of oral contraceptives based on only one menstrual cycle (15).

Lapin and Oxenkrug (45) have postulated that the induction of tryptophan oxygenase by cortisol may result in the shunting of available tryptophan to the kynurenine-niacin pathway and away from the indole pathway, thereby lowering the level of brain serotonin, and that this may be related to the onset of depression. Daily injections of hydrocortisone have been shown to lower the concentrations of serotonin in rat brain; these revert to normal after about five days (46), no doubt due to adaptive mechanisms, one of which is probably the fact that hydrocortisone also induces tryptophan hydroxylase (47). Benkert and Matussek (48) were unable to duplicate this experiment. Since estrogen is known to increase the concentration of circulating cortisol (49) and also to induce tryptophan oxygenase in rats whose ovaries and adrenal glands have been removed (50), it has been suggested that oral contraceptives may lower the concentration of brain serotonin by a similar mechanism (51). Female rats given daily injections of a combination of norethynodrel and mestranol were found to have significantly lower levels of brain serotonin after ten days, but normal levels after 20 days (52). However, the finding that a decrease in the concentration of serotonin of about 50 percent occurs at estrus in rodents (53) suggests a possible source of error in this experiment.

Mason and associates (43) have examined several vitamin B_6-dependent enzyme systems in the tryptophan-

kynurenine-niacin pathway and suggest that estrogen conjugates compete with pyridoxal phosphate for binding sites on the apoenzymes kynureninase and kynurenine transaminase. Since the transaminase is less sensitive to a deficiency of pyridoxal phosphate, xanthurenic acid accumulates; the amount of xanthurenic acid excreted in the urine after the administration of a loading dose of tryptophan is therefore used as an index of pyridoxine deficiency (54). In view of the fact that estrogen conjugates have been shown to inhibit the induction of 5-hydroxytryptophan (5-HTP) decarboxylase in vitro (55), it is not unreasonable to suppose that a similar situation may exist in vivo along the indole pathway; this would reduce the levels of brain serotonin, the synthesis of which is pyridoxine-dependent. Since the enzyme that decarboxylates dopa is also pyridoxine-dependent and is thought to be the same enzyme that decarboxylates 5-HTP (56), catecholamine concentrations may be similarly affected. Four women who were taking oral contraceptives demonstrated a reduction in urinary excretion of catecholamine metabolites (6). In another study, seven women taking oral contraceptives showed alterations in their excretion of catecholamine metabolites, but there was no consistent pattern (8).

It has been shown that up to 25 mg. of pyridoxine daily is required to correct the metabolism of tryptophan along the kynurenine-niacin pathway in women taking oral contraceptives (33, 34, 44). Since the normal diet contains approximately 2 mg. of pyridoxine daily, there is some evidence that oral contraceptives markedly interfere with the proper use of, or increase the need for, pyridoxine.

In view of some of the above considerations, a few women who had developed depression during pregnancy or while taking oral contraceptives were given 50 mg. of pyridoxine daily with apparently favorable results (57, 58). In one case, reduction of the dose to 25 mg. daily resulted in a return of depression that lifted when the dose was increased to 35 mg. Another patient, who required 25 mg. while taking oral contraceptives (58), required 100 mg. during a later pregnancy and 50 mg. daily ten months after delivery, even though she was no longer taking oral contraceptives.

DISCUSSION

The results of a preliminary uncontrolled trial (59) were encouraging enough to indicate the need for placebo-controlled double-blind studies of the effect of pyridoxine on women who complain of the onset or worsening of depression after starting to take oral contraceptives.

The mode of action of pyridoxine is more difficult to determine, since it is impossible to measure changes in the concentrations of amines in the human brain. However, inferences can be drawn from the urinary excretion of indoleamines and catecholamines after the administration of loading doses of tryptophan and L-dopa to depressed women who are taking oral contraceptives with and without pyridoxine. Although this will not necessarily reflect amine activity in the brain, it will be significant if any consistent changes (such as the increased excretion of 5-HTP) are found to correlate with the degree of observed depression. Experiments with 5-HTP labeled with ^{14}C, as developed by Coppen and associates (60), may give information on any possible interference with decarboxylation. Functional pyridoxine deficiency may have no direct effect on the indole pathway, but the serotonin levels might be lowered because of an increase in the amounts of circulating kynurenine and hydroxykynurenine, injections of which have been shown to lower serotonin concentrations in rat brain (61). The concurrent administration of pyridoxine and hydrocortisone does not prevent the reduction of concentrations of serotonin in rat brain (62). This experiment might well be repeated with estrogen injections. However, as has previously been pointed out (51, 62), experiments in rat brain may not be strictly relevant, since the levels of 5-HTP decarboxylase in human brain would appear to be much lower than those in the rat and since the enzyme that controls the rate of synthesis of serotonin in human brain may be 5-HTP decarboxylase rather than tryptophan hydroxylase (63).

Estrogen-induced disturbance of the metabolism of tryptophan is a general effect and cannot in itself be regarded as the cause of depression in women taking oral contraceptives since only a small percentage of women are adversely affected. The development of clinical symptoms probably depends on the failure of the usual regulatory mechanisms. There is evidence that the level of MAO activity is dependent on sex hormones (64), that there is some correlation between peripheral and central MAO activity, and that estrogen may have MAO-inhibiting properties (65). The relief of premenstrual depression in many women who are taking oral contraceptives may be related to this. However, the balance of the effects of estrogen on biogenic amine levels may also depend on the state of enzyme activity at the time of administration and may be dose-related. Depressed women being treated with imipramine appeared to benefit from the addition of 25 μg. of ethinyl estradiol daily, whereas 50 μg. daily produced an adverse effect (66).

Serotonin concentrations in most women might be high enough to allow for some reduction without the appearance of any clinical symptoms, or the concentration might be maintained by a reduction of MAO activity in response to the lowering of the substrate (serotonin). Conceivably the suggested MAO-inhibiting property of estrogen might cancel out any slowing of amine synthesis under normal conditions. Alternatively, the levels of 5-HTP decarboxylase in the brain may normally be high enough to allow for moderate inhibition without any noticeable effect on serotonin levels. However, there may be some women with unusually low concentrations of 5-HTP decarboxylase in the brain who are particularly sensitive to pyridoxine deficiency. The finding that depressed patients have low concentrations of 5-HIAA in their cerebrospinal fluid, not only when ill but long after recovery (28), suggests that their level of amine synthesis re-

mains low, with a corresponding reduction in MAO activity, and that their levels of serotonin may be marginal. In such a patient the further inhibition of amine synthesis, e.g., as a result of taking oral contraceptives, may precipitate the appearance of clinical symptoms, since further regulation may not be possible. It is in this situation that supplementary pyridoxine may be able to prevent any adverse effects on mood.

However, in view of the many decarboxylase and transaminase reactions that are pyridoxine-dependent, it is unlikely that functional pyridoxine deficiency would manifest itself in only one clinical symptom, i.e., depression, and consideration must be given to the possibility that it contributes to other side effects of oral contraceptives (34, 67).

The administration of pyridoxine (68) has been shown to improve the impaired glucose tolerance curve frequently observed in women taking oral contraceptives (69), possibly by reducing the formation of excess xanthurenic acid, which has been shown to combine with circulating insulin to form a complex that reduces its effect on the blood glucose level (70).

Clinical experience (71) suggests that women with severe premenstrual depression and a history of previous depressive disorder and/or depression during pregnancy and whose symptoms become worse after they begin to use oral contraceptives are those who are most likely to respond to pyridoxine. This would appear to be the same group of women Herzberg and associates (12) described as those most likely to become depressed while using oral contraceptives. Of 250 such women, 220 appeared to show a good response to pyridoxine under uncontrolled conditions; many of these women continued to take pyridoxine after discontinuing the use of oral contraceptives (71). This suggests that a number of women with premenstrual depression that is not associated with the use of oral contraceptives will be found to be pyridoxine responders. However, women in this group form a very small percentage of the total number of women with premenstrual depression. In a controlled study of the effect of pyridoxine on premenstrual depression that was not associated with the use of oral contraceptives (and that excluded those women whose symptoms were severe enough to require psychoactive medication), only one out of 13 women showed significant improvement and one became worse (72, 73). This result lends support to the view that premenstrual depression in normal women is not significantly associated with impaired amine synthesis but that this may be the case with women who respond to pyridoxine.

In a recent double-blind crossover trial of the effect of pyridoxine on depression that *was* associated with the use of oral contraceptives, by women who had no previous history of psychiatric illness, 11 of 22 women showed biochemical evidence of absolute (as opposed to relative) vitamin B_6 deficiency.[1] The administration of supplementary pyridoxine significantly relieved the depressive symptoms of the 11 members of this subgroup but had no effect on the remainder (74).

[1] The term "absolute vitamin B_6 deficiency" is used in this context to imply the existence of a subnormal level of pyridoxal phosphate in tissues.

Subjects' Recent Life Changes and Coronary Heart Disease in Finland

BY CDR. RICHARD H. RAHE, MC, USNR, LINDA BENNETT, MATTI ROMO, M.D., PENTTI SILTANEN, M.D., AND CAPT. RANSOM J. ARTHUR, MC, USN

Data on recent life changes were gathered for 279 survivors of myocardial infarction and 226 victims of sudden coronary death in Helsinki, Finland. Subjects in both groups experienced a significant increase in recent life changes during the six months prior to infarction or death compared with the same six-month period one year earlier. Subjects were compared according to whether they had shown marked, moderate, or no increase in recent life changes. The authors point out the usefulness of including data on precipitating factors in prospective studies of coronary heart disease along with data on such physical risk factors as serum cholesterol levels and systolic blood pressure.

MORE THAN TWO DECADES of epidemiologic research, both in the United States and in Europe, have resulted in the identification of a number of "risk factors" that seemingly predispose certain people to the development of coronary heart disease (1–3). Among these factors are serum cholesterol levels, blood pressure, degree of body fat, and cigarette smoking, as well as selected psychological traits concerning competitiveness, a "driven" quality, and a feeling of the urgency of time. With the possible exception of cigarette smoking, these factors are not considered to be precipitants of coronary crises such as myocardial infarction or sudden coronary death (4).

Recent changes in subjects' lives have shown promise as possible precipitating factors in a number of disease entities, including coronary heart disease (5–8). Survivors of myocardial infarction have reported significantly more life changes over the final six months before the infarction than during comparable intervals of time a year or two earlier. In addition, reports by the spouses of the victims of sudden coronary death have noted significant increases in recent life changes during the six-month period immediately before death compared with corresponding six-month periods one or two years earlier. Since these previous investigations were carried out with relatively small samples, the present study was designed as an attempt to replicate these previous findings, using a sample of over 500 persons. Finland proved to be the ideal country for such a study for two reasons: 1) the cooperation given to medical examiners by Scandinavians is excellent, and 2) Finland has been shown to have rates of incidence and prevalence of coronary heart disease that are among the world's highest (9).

Cdr. Rahe, Ms. Bennett, and Capt. Arthur are with the U.S. Navy Medical Neuropsychiatric Research Unit, San Diego, Calif. 92152, where Cdr. Rahe is Head of the Biochemical Correlates Division, Ms. Bennett is Research Associate, and Capt. Arthur is Commanding Officer. Dr. Romo is Principal Investigator of the Ischemic Heart Disease Register and Dr. Siltanen is Medical Director of the Finnish Heart Association, Helsinki, Finland.

This work was supported in part by the Bureau of Medicine and Surgery, Department of the Navy, under Research Work Unit MR011.01-6110 1N, and in part by the Signe and Ane Gyllenberg Foundation, Helsinki, Finland.

The authors wish to thank Heikki and Seija Arajärvi, who coordinated the Finnish translation of the Schedule of Recent Experience questionnaire; Kyllikki Miettinen, Tuula Lilnanto, and Sirkka Laakso, the nurse-interviewers; and Marita Puranen, who provided secretarial assistance.

The opinions expressed herein are those of the authors and do not necessarily reflect the views or endorsement of the Department of the Navy.

METHOD

The Finnish Heart Association, in cooperation with the World Health Organization, set up an Ischemic Heart Disease Register in September 1969 that has been maintained up to the present. Virtually all cases of acute ischemic heart disease occurring in the inhabitants of Helsinki have been registered. The criteria for the diagnosis of acute ischemic heart disease are those that have been outlined by a subcommittee of the World Health Organization and are common to all ischemic heart disease registers used in several European countries (10).

Measurements of subjects' recent life changes were carried out by nurse-interviewers who used a Finnish translation of the Schedule of Recent Experience (SRE) questionnaire. This questionnaire, described in detail in previous reports (5–8), is composed of 42 life-change questions. Respondents indicate which, if any, of the 42 life changes they may have recently experienced and in which three-month interval over the past two years these events occurred.

As in previous studies with the SRE, the life changes themselves were scaled to obtain life-change unit (LCU) weights for the individual items (5–8). These LCU weights represent the average degrees of life change and readjustment necessary for an individual to cope with each life event. Even though previous studies of persons living in various countries (11, 12) have indicated a high degree of agreement on these LCU weights, and especially on the rank ordering of the 42 life changes by LCU weights, a rescaling of the life changes was carried out in Finland on a separate sample of 149 subjects. The results of this Finnish scaling study are shown in table 1. (Finns

who took part in the LCU scaling experiment were healthy men and women covering a wide age range; none of the persons whose names were gathered from the Ischemic Heart Disease Register participated in the scaling.)

There were 292 nearly consecutive entries in the Helsinki Ischemic Heart Disease Register for persons who had survived a definitive myocardial infarction and were less than 65 years of age. Complete information on the SRE questionnaire was collected from 279, or 95 percent of all possible subjects; the remaining five percent were either too ill to cooperate or refused cooperation. During approximately the same time period, the names of 286 subjects who were less than 65 years of age and had died abruptly of coronary heart disease were gathered from the register. The spouses of these persons, or on rare occasions a close relative, were contacted for interview with the SRE questionnaire. Twenty-five of the 286 subjects proved to have no spouse or close relatives from whom information on life changes could be obtained. An additional 24 subjects did have such a relative, but the interviewers were unable to make contact with them. Only 11 relatives who were contacted refused the interview. Hence, complete data on life changes were collected for 226 persons who died of coronary heart disease, or 79 percent of all possible cases; in only five percent of the cases did relatives who were contacted refuse to be interviewed.

On the basis of the results of previous investigations, it was hypothesized that subjects who had a myocardial infarction or an abrupt coronary death would reveal an increase in LCU totals during the two years prior to their infarction or death (6–8). Because of this hypothesis, as well as the fact that LCU comparisons were made between six-month periods for the same groups of persons, the one-tailed t test for correlated means was used. For intergroup comparisons, however, the standard two-tailed t test was used.

TABLE 1
Life Change Events and Their LCU Weights Scaled for Finland

Event	Finnish LCU Weight
HEALTH	
Recent illness (in bed for a week or hospitalization)	62
Change in heavy physical work or exercise	19
Change in sleeping habits	15
Change in eating habits	11
WORK	
Recently out of work	50
Recently fired from work	50
Retirement from farming, forestry, or industry	40
Change to new type of work	36
Change in work responsibilities	29

Death of a close friend	34
Unpaid bills leading to threatened legal action	26
Recent purchases worth more than 8,000 Fmk ($2,000)	22
Change in religious or political convictions	20
Change in personal habits	12
Recent purchases worth less than 8,000 Fmk	11
Minor violations of the law	7

RESULTS

Myocardial Infarction and Recent Life Changes

Since it had been previously demonstrated that a person experiences more life changes several months before, and after, major illness or injury (13), it was important to divide the 279 survivors of a definitive myocardial infarction into two subgroups on the basis of their physical health during the two years prior to their infarctions. We found that 113 subjects had suffered a significant illness, generally of cardiovascular origin, during the two years prior to their infarctions. The remaining 166 subjects recalled no illnesses during the two years before their infarctions. Only in the cases of subjects who had been in good health during the two years before their infarctions could an increase in the number of recent life changes be clearly unrelated to other physical illness or injuries. (In Scandinavian samples, many life changes are determined by the season of the year, e.g., vacations in July, overwork during winter; the interval most comparable to a given six-month period, therefore, is the same six-month period in the preceding year.)

As shown in table 2, the mean LCU totals for the final six months for survivors of myocardial infarction with preinfarction illnesses was 74 LCU. The mean LCU total for this group of subjects during the comparable six-month period one year earlier was 52 LCU. This 42 percent increase in the six-month LCU total was significant at the level of $p<.025$. Similarly, survivors of myocardial infarction who were in good health during the two years

TABLE 2
Comparison of Six-Month LCU Totals

Group	Number	Final Six-Month LCU Totals (Mean ± S.E.)	Six-Month LCU Totals One Year Earlier (Mean ± S.E.)	Significance
Survivors of myocardial infarction				
Recent illness	113	74 ± 6.2	52 ± 6.2	$p < .025$
No recent illness	166	39 ± 3.9	23 ± 2.8	$p < .005$
Sudden death				
Recent illness	65	77 ± 7.7	44 ± 7.8	$p < .005$
No recent illness	61	51 ± 8.0	21 ± 4.2	$p < .005$
Delayed death				
Recent illness	49	96 ± 11.7	56 ± 9.1	$p < .025$
No recent illness	35	42 ± 7.7	35 ± 10.2	n.s.

prior to their infarctions had a mean LCU total for the final six months of 39 LCU, compared with a mean LCU total of 23 for the comparable six-month period one year earlier. This 69 percent increase in the subjects' mean six-month LCU total was significant at the $p<.005$ level of confidence.

Intergroup comparisons between survivors of myocardial infarction with and without preinfarction illnesses indicated that those with preinfarction illnesses had significantly higher six-month LCU totals for both the six months immediately prior to the infarction and for the six-month interval one year earlier than did their counterparts who reported good health prior to their infarctions ($p<.01$).

Acute Coronary Death and Recent Life Changes

There were 126 subjects who died within an hour of their initial onset of symptoms. This subsample was called the "sudden death" group and was itself divisible into 61 subjects who had apparently been healthy during the two years prior to their sudden death and 65 subjects who reportedly experienced significant illnesses during this two-year period. There were 100 subjects who died of their acute coronary episode between one hour and 28 days after the onset of symptoms; they were labeled the "delayed death" group and were divided into 35 subjects who had apparently suffered no significant illness and 49 who reportedly did experience illnesses during the two years prior to death (the remaining 16 subjects in the delayed death group had possibly died of causes other than their coronary heart disease, e.g., renal failure, and were therefore excluded from the following analyses).

Table 2 shows that, for sudden death subjects who experienced illnesses during the two years before their deaths, the mean LCU total for the final six months was 77. Their mean LCU total for the six-month period one year earlier was 44. This 79 percent increase in the LCU total was statistically significant ($p<.005$). Sudden death subjects with no illnesses during the two years before their deaths had a mean LCU total for the final six months of 51. In comparison with their mean LCU total for the six-month period one year earlier, which was 21, these subjects showed a 143 percent LCU increase ($p<.005$).

Intergroup comparisons between the two subsamples of sudden death subjects indicated that, for both six-month periods under study, those who had prior illnesses had significantly higher LCU totals than did their counterparts who had no recent illnesses ($p<.025$).

Finally, table 2 indicates that, for the delayed death subjects with previous illness during the two years before death, a 71 percent LCU increase (from 56 to 96) was seen over the two six-month periods under study ($p<.025$). Delayed death subjects with no recent illnesses showed an increase in six-month LCU totals of only 20 percent (35 to 42), which was not statistically significant.

Intergroup comparisons showed that only for the six-month period immediately before death did the delayed death subjects who had prior illnesses demonstrate a significantly higher mean six-month LCU total than subjects who had reportedly experienced no illnesses before death ($p<.01$).

Degree of Increase in Recent Life Changes

Not all survivors of myocardial infarction or coronary death subjects showed an increase in final six-month LCU totals. Some persons experienced a marked increase; others reported slight to moderate increases. In order to examine the distribution of subjects according to their recent increases in LCU totals, only survivors of myocardial infarction and coronary death subjects with no premorbid illnesses during the two years under study were compared. In this way, all life changes reported up to the time of infarction or death were presumably due to the subjects' accustomed activities of middle age rather than the result of previous illnesses. Finally, criteria were established for what constituted "marked," "moderate," and "no" final six-month LCU increases.

There were 166 survivors of myocardial infarction who reported no preinfarction illnesses; 96 coronary death subjects reportedly experienced no illness during the two years prior to their deaths. A marked increase in recent life changes was defined as an increase in the final six-month LCU total of at least 100 percent over the six-

TABLE 3
Comparison of Increase in Recent Life Changes, in Percentages

Marked	29	38
Moderate	35	33
None	36	29

month LCU total for the same interval one year earlier. In addition, subjects were included in this category if their LCU totals were zero for the final six-month period of the previous year and were 26 or more for the final six months before myocardial infarction or death. (An increase of 26 was the mean LCU increase for those subjects who reported a final six-month LCU increase of 100 percent.)

Moderate increase in recent life changes was defined as an LCU increase of one to 99 percent for the final six-month period over that for the corresponding period one year earlier. In addition, subjects were included in this category if their LCU totals were zero for the final six months of the previous year and were from one to 25 LCU for the final six months of the study period. Also included in this category were those few subjects whose LCU totals were 26 or more for the final six months of the previous year (an "early" LCU elevation), although their six-month LCU totals for the final year were 25 or less.

The remaining subjects comprised the group with no recent increase in life changes—those who reported 0–25 LCU for the final half of the previous year and an equal or smaller LCU total for the six-month period immediately prior to myocardial infarction or coronary death.

The percentages of subjects falling into each of the three divisions outlined above are shown in table 3. It can be seen that subjects with a "marked" increase in recent life changes accounted for 29 percent of the myocardial infarction group and 38 percent of the coronary death group, whereas for subjects with "no" recent life changes these percentages were, in effect, reversed.

DISCUSSION

Survivors of myocardial infarction demonstrated significant increases (42 to 69 percent) in their final six-month LCU totals over those for the corresponding interval one year earlier. This final six-month LCU increase was seen despite a relatively high six-month LCU total for the final half of the earlier year for those subjects with recent illnesses. Hence, whatever the subjects' LCU "baseline," a relative increase in their LCU totals appeared to herald the onset of new coronary disease.

With the exception of the relatively small subgroup (N=35) of delayed death subjects who experienced no recent illnesses prior to their deaths, significant increases were also seen for sudden and delayed death subjects in their final six-month LCU totals. The two sudden death subsamples and the delayed death subsample with recent illnesses reported increases of 71 to 143 percent in their final six-month LCU totals compared with the same period one year earlier. It appeared, then, that those subjects with the most severe coronary crises—sudden death—reported the highest increases in recent life changes, delayed death subjects reported the next highest, and survivors of myocardial infarction reported the smallest increases in recent life changes. As was the case for survivors of infarction, the coronary death subjects with recent illnesses showed higher LCU totals during the two years under study than did those who were in good health during this time.

The demonstration of a significant increase in recent life changes for both survivors of myocardial infarction and coronary death subjects during their final six months before infarction or death implies a precipitating influence of these life changes upon the onset of their illness or death. It would seem to follow that if many of these subjects had not been exposed to this significant increase in demands on their lives, they might not have developed an infarct or have died at the time that they did.

An examination of the percentages of selected Finnish survivors of infarction and coronary death subjects who experienced marked, moderate, or no recent increases in life changes can be compared with the percentages of myocardial infarction and sudden death subjects who showed marked, moderate, or no elevations of serum cholesterol or systolic blood pressure. Data for these two well-established "physical" risk factors for coronary heart disease have been taken from a large American prospective study of 3,049 middle-aged men followed for the development of coronary heart disease over four and a half years (14). Two hundred of these American men developed a definitive myocardial infarction; 57 others died of coronary heart disease during the follow-up period. Table 4 shows the percentages of these survivors of myocardial infarction and coronary death subjects who

LIBRARY

demonstrated marked, moderate, or no elevations of their serum cholesterol and systolic blood pressure. (Marked serum cholesterol elevations were defined as those above 259 mg./100 cc., moderate values were between 220 and 259 mg./100 cc., and low values were those less than 220 mg./100 cc. Similarly, marked systolic blood pressure elevations were defined as those greater than 159 mm. Hg; moderate values were between 120 and 159 mm. Hg; and low values were those less than 120 mm. Hg.)

Subjects with markedly elevated serum cholesterol levels accounted for 31 percent of survivors of myocardial infarction and 51 percent of coronary death subjects, while those with low levels accounted for 33 percent and nine percent, respectively. Subjects with marked elevations in systolic blood pressure accounted for 14 percent of each group, while those with low levels accounted for 16 percent of survivors of myocardial infarction and 14 percent of coronary death subjects. Thus, although not all of our Finnish subjects reported marked or moderate increases in recent life changes prior to infarction or death, the case is only slightly better for the distribution of the two important physical risk factors documented in the American study.

In the study by Rosenman and associates (14), of all subjects whose systolic blood pressure was greater than 159 mm.Hg., approximately 5.4 percent developed an infarction and/or coronary death during each follow-up year. Of all the subjects whose serum cholesterol values were greater than 259 mg./100 cc., approximately 3.1 percent developed an infarction and/or coronary death during each of the follow-up years. Hence, between 95 and 97 percent of all subjects with markedly high values for either of these two physical risk factors for coronary heart disease do *not* develop myocardial infarction or coronary death the following year. It may therefore be useful to include such possible precipitating factors as subjects' recent life changes in future prospective studies of coronary heart disease, since they may predict higher percentages of subjects who will develop myocardial infarction or coronary death during the following year than is possible with the currently used risk factors.

Pediatric-Child Psychiatry Collaboration in a Health Maintenance Organization

BY NORTON GARBER, M.D.

The author describes a collaborative program between the child psychiatry and pediatric services of a prepaid group practice plan that included weekly meetings between the psychiatrist and the pediatric staff, meetings also involving other disciplines, and clinical evaluations of referred patients. The advantages of this kind of approach, especially its educational and preventive aspects, are described, and it is proposed as a possible model for interdisciplinary work that will help realize the goal of comprehensive health care.

THE CURRENT CRISIS in health care delivery has generated wide interest and debate. Political, financial, and philosophical issues have influenced proposed solutions and overshadowed medical considerations, while even in medical discussions the focus has been on statistical rather than clinical issues. As a reflection of this, the future role and function of psychiatry and child psychiatry as well as other disciplines remain quite unclear. What is no longer in doubt, however, is that change in our systems of health care delivery is forthcoming. Therefore, what is needed to contribute to a more relevant and meaningful discussion is an examination of clinical experience in those systems which are now being promulgated as "new" solutions to this crisis.

The health maintenance organization (HMO), which in practice is usually a prepaid group practice medical care program, is one such system that has provided new opportunities to explore health care services. Recent reports (1, 2) have reviewed the utilization and feasibility of child psychiatry within an HMO. This report, which will focus on the HMO as a unique setting for pediatric-child psychiatry collaboration, will describe and evaluate this collaboration as a new working model of health care services for children.

Comprehensive medical care of the child has been defined as:

> the prevention and treatment of physical disease, and the supervision of healthy growth and development, physical and psychological. Through his comprehension of the physical, psychological, and social forces that influence the child, the pediatrician enables the child and his family to take an active role in solving their health problems (3).

Dr. Garber is Assistant Clinical Professor, Yale Child Study Center, and Staff Psychiatrist, Yale University Health Services, Division of Mental Hygiene, Box 1505-A, Yale Station, New Haven, Conn. 06520.

This approach demands an involvement by pediatrics with psychiatry in mastering the psychological developmental aspects of child care and points in the direction of a true collaboration for comprehensive pediatric care.

The child psychiatrist has always had an interest in collaborative work with pediatricians. There are several reasons for this: First, his training may have had a collaborative emphasis, for in most training centers the child psychiatry fellow works as a consultant to the pediatric house staff on the wards and in the clinics. Second, this training has a distinct developmental orientation, which means (among other things) that the child psychiatrist shares with the pediatrician the necessity for a vital appreciation and active consideration of the growing child in physical health as well as illness. Also, since psychological disturbances in childhood are often intimately involved with disruptions in physiological functioning and development, pediatrician and child psychiatrist are drawn together once more. Finally, with both disciplines firmly anchored on principles of growth and development, they share the concept of prevention as an active, daily concern.

In spite of this, our systems of private practice and child guidance clinics have often poorly served the interests of comprehensive pediatric care. They have operated too often in a fragmented fashion in which referral to the psychological specialist substitutes for meaningful collaboration.

The objectives of health maintenance organizations include the maintenance of health and the prevention of disease; these goals are pursued through the team practice of medicine, which has mechanisms to integrate a disjointed, overspecialized, and uncoordinated health care delivery system (4). The health maintenance objective carries with it the necessity for the primary physician to expand his information and awareness as he shifts away from a "medical crisis" focus. The team practice concept necessitates the exploration and application of new approaches to health care and the assimilation of experience in new ways.

The obvious congruity between the objectives of health maintenance organizations and the expertise, interest, and experience of the child psychiatrist should lead toward the establishment of a truly coordinated and comprehensive child health maintenance program that promotes normal growth and development. Such a program might be produced by a team consisting of the pediatrician working in collaboration with the child psychiatrist. The opportunity to apply these ideas in a working model became available with the establishment of the new Yale Health Service.

SETTING

The Yale Health Service is a voluntary prepaid group practice medical care facility that opened on July 9, 1971. Sponsored by the university, it offers complete medical facilities and services provided mainly by a full-time staff of physicians with university appointments. A 66-bed intermediate care facility is housed within the building; care for more serious illness is provided through insurance coverage. Psychiatric consultation and evaluation is offered for adults and children; if there is referral for private therapy the patient pays part of the cost under a coinsurance arrangement. The average pediatric population this first year was 2,807, consisting of 37 percent employee children, 52 percent faculty children, and 11 percent student children.

The pediatric service includes four Yale-trained pediatricians and one nurse practitioner. One pediatrician had had many years of experience in private practice, another had been director of pediatric outpatient services at Yale-New Haven Hospital, a third had recently returned from postresidency military service, and the fourth had just completed his pediatric residency training. The nurse practitioner had had approximately six months' experience in a hospital clinic and private pediatric office. As the child psychiatrist, I had had three years' experience in private practice and in the Yale Department of University Health. During this first year of the service I devoted ten hours weekly to the pediatric-child psychiatry collaboration.

GOALS AND OBJECTIVES

Whereas the adult and student psychiatric division of the Yale Health Service had previously existed as part of the predecessor Department of University Health, both the child psychiatry and pediatric services were new. This largely freed us from the bonds of precedent but it also deprived us of the background experience that can be helpful in developing such services. We were uncertain as to what demand for service would emerge from the population, especially since we knew of no comparable population in an HMO. Although utilization was hard to predict, we spent considerable time trying to delineate the goals and the mode of operation for child psychiatry. A statement of policy and procedures that discouraged self-referral and encouraged initial pediatric consultation was devised and circulated to the staff. It read in part:

> [The policy] is designed to deliver the best possible psychiatric service to dependent patients under 18 years of age within the limits of available child psychiatric time. It provides for prompt direct consultative services for psychiatric disorders. In addition, it is an attempt to move towards a true comprehensive approach to child care on the part of the pediatric service which, hopefully, will respond increasingly to stress situations in psychological development before the occurrence of true psychiatric crises.

An initial decision was made to use this first year as a period to evaluate needs and objectives. Notes were kept on all the discussions that took place during the year and were reviewed at the year's end.

THE OPENING PHASE

During the first month I made a particular effort to establish collaboration as a vital and routine part of the pediatricians' work. Although collaboration as such was not foreign to any of them it still seemed important for me to prove its worth once again. I tried to accomplish this in three ways. First, I had to offer something that was needed, so I offered to accept referrals for psychiatric evaluation, thereby fulfilling a need of which they were well aware. Second, I sought their aid in planning and setting up the collaboration. Active and enthusiastic participation in such a program depends partly on sharing the formulation of the program so that it is felt to be truly "our" program. Finally, if I was to expect their interest in a psychological viewpoint I had to demonstrate my interest in their pediatric work. For this reason, and because I wanted to watch each of them work as well as refresh my own pediatric experience, I spent most of my time during the first month observing the pediatric staff in their work. My interest in observing their daily work could also be expected to reinforce their appreciation of the importance of their "routine" contacts with the children. From a psychological viewpoint no experience between a child and a pediatrician is routine.

METHODS OF COLLABORATION

During the course of the year, pediatric-child psychiatry collaboration assumed four forms: one-hour weekly meetings with the pediatric staff, ad hoc team meetings that included other disciplines as well as pediatrics, one-to-one meetings with individual pediatric staff members, and clinical evaluation of referred patients.

The weekly meeting quickly assumed the pivotal role in our collaboration. A determining factor was the relative inviolability of the time: this was the only time during the week that the pediatricians were freed from direct clinical demands. Establishing this "sacred" period of time, which was partly a result of my insistence, reflected my own appreciation of its importance; it was an appreciation gained through my own work with patients in psychotherapy. The meeting provided a forum for exchange of views and feelings among the staff, fulfilling their need not only to discuss patients and consider possible psychiatric referrals but to raise clinical developmental problems that emerged in their work. At times there were issues that called upon my expertise in child psychiatry but equally often there was an open discussion eliciting the experience of the pediatricians themselves. Often a case would be followed for several weeks while suggestions were offered for interview techniques and the synthesis of material.

The following brief notes convey some of the sense of these discussions:

> Parents requested guidance for sleep disorder in a 2½-year-old child whose younger sibling had recently died. The discussion included an understanding of the meaning of death for a 2½-year-old, considerations of separation anxiety, and the parents' own emotional state. Further symptomatology (hysterical crying, increase in masturbation) was revealed through a review of the child's clinical status. The question of what support the pediatrician can give the parents and what they are actually asking for was discussed.

> Advice on toilet training. Should the pediatrician initiate this discussion with parents and, if so, at what point? How active a role should the pediatrician take? What should he say to the parents and what, in turn, should the parents say and do with the child? How actively involved should he get?

> On a routine visit for annual physical examinations a mother mentioned that she and her husband were separating. Brief questioning by the pediatrician revealed that visitation rights for the 6-year-old and 2-year-old were likely to become issues of contention. What considerations of child advocacy and developmental factors are important in outlining an appropriate visitation procedure? What is the obligation of the pediatrician to advise and educate the parents regarding these developmental factors, and what is the possibility of offering them his auspices as an alternative to a legal forum?

The psychiatrist and individual pediatricians had frequent informal meetings, particularly to discuss specific findings following the psychiatric evaluation of a child. We tried to answer the referring questions as well as to discuss recommendations for further medical or psychiatric management. At times specific issues in clinical diagnosis were also reviewed informally on a one-to-one basis. In adapting to a pediatric practice rhythm I made an effort to keep time open to encourage informal contacts.

The general areas covered in our discussions included the following:

1. Management of normal developmental crises by pediatrician and/or parent—e.g., toilet training.
2. Reaction of parent to illness, death, or physical defect of child or sibling.
3. Reaction of child to physical illness or defect of parent or sibling.
4. Reaction of child to his own physical illness or defect.
5. Psychophysiological developmental disturbances—e.g., enuresis, encopresis, sleep or eating disorder.
6. Somatic disorders—e.g., asthma.
7. Parental adjustment to the changing role of the adolescent in the family.
8. Changes in the security of the household—e.g., frequent moves and lengthy periods in a foreign environment.
9. Disruption of the parental coalition.

As the year progressed it became clear that certain clinical problems demanded evaluations that routinely involved other disciplines: neurology, psychology, otolaryngology, ophthalmology, and learning specialties. These clinical difficulties included developmental problems of infancy, visual and auditory disorders, and learning disorders. Our first effort at a team approach, which dealt with learning disorders, was put into effect under the coordination of the pediatrician. It involved pediatrics, psychiatry, psychology, nursing, ophthalmology, and optometry. The approach evolved from a series of meetings in which we educated ourselves through readings, discussions, and lectures by outside experts. After reviewing and pooling our experiences, we formulated a team evaluation approach. This provided for an initial developmental screening by the pediatric nurse practitioner, and then evaluations by the pediatrics, ophthalmology, psychology, and psychiatry services—all coordinated by the pediatrician.

Finally, I conducted clinical evaluations of 30 referred patients, seeing all the children and family members personally. The effectiveness of the screening and referral practices of the pediatrics service was reflected in the appropriateness of the referrals, in the fact that there was only one dropout following referral, and in our impression that almost all of the patient families accepted the final recommendations well. I found it helpful to have heard something about the families from the pediatricians beforehand and to have received before evaluation a preliminary information sheet given the families by the pediatrician and completed by them.

UTILIZATION OF THE EVALUATION SERVICE

A total of 30 children and their families were seen directly for psychiatric evaluation. This represented approximately half the cases discussed in my weekly meetings with the pediatricians. The utilization rate for psychiatric evaluation was 10.6 per thousand enrollees per year.[1] Of these, 26 were referred by pediatrics and the rest were self-referred. The average number of sessions per evaluation was 3.7. Further therapy was recommended for 17 of the 30.

These statistics may reflect certain conditions prevailing only in the first year of the service; these would include the existence of families who were waiting for the opening of the service to request help for long-standing problems. But this might have been counter-balanced by the lag before the pediatricians became sufficiently acquainted with their patients to be able to detect difficulties and prepare them for referral.

DISCUSSION

On the basis of this first year's experience a number of features have emerged that reaffirm the importance of such a collaboration, demonstrate the advantages of such

[1] Other studies, while not altogether comparable, showed rates per 1,000 enrolled population of 12.6 per year (1), 10 per year (5) and 70 over three years (6).

work in an HMO setting, and suggest this kind of collaboration as a model for comprehensive health service. Among the advantages are:

1. The possibility for a more effective application of clinical services for many (if not most) clinical problems because of increased flexibility, continuity, and feedback. The pediatrician remains a constant figure available to the child, overseeing his development and coordinating additional information. Psychiatric problems are less likely to be seen as a signal for referral to another physician or clinic than as an opportunity for concerted, collaborative effort and evaluation.

2. More efficient, more appropriate, and more specific use of child psychiatric time, with concomitantly greater use of other qualified personnel, including nurse practitioners.

3. A coordinated team approach to certain combined clinical entities, thus avoiding the fragmentation, confusion, and delay often encountered when individual practitioners or agencies are involved.

4. The emergence of significant patterns when we were confronted in our meetings with the way in which certain parents sought medical advice for a child and what they then did with this advice. For example, a mother's behavior in consulting one specialist after another was explored in terms of her need to avoid confronting her child's defect and her identification with it. We also explored the physician's reaction to a patient who did not follow his advice but sought "better" advice. Once again, the availability of a unified medical record documented and dramatized such a pattern and made it more difficult to overlook.

5. Greatly enhanced opportunities for education. In the weekly meeting with the pediatric staff I tried to transmit those principles of psychiatric technique and theory that would be directly useful to them. Early intervention and prevention were stressed through exploration of issues of cause and effect and patterns of normal development. We discussed interview techniques, observational skills, and the kind of synthesis of this material that is necessary for a psychological formulation. The meeting also served as a forum for pediatric peer supervision, which was supportive and helped to reduce pressures toward isolation (7). The regular feedback of information from the evaluations to the pediatricians could be used not only in guiding them in their further pediatric work with a particular patient but in aiding them to sharpen their own psychological evaluative skills.

6. Many opportunities for studying the impact of various interventions. Since an HMO provides a defined population, efforts to move toward prevention and early intervention should eventually be reflected in a decrease in significant psychopathology needing psychiatric evaluation. Similarly, clinical hypotheses can more easily be tested because of the availability of centralized information. For example, in reviewing the material discussed by the pediatricians this past year I discovered relatively little discussion of children with chronic illness who ordinarily would be expected to present problems in psychological development. Whereas an observation like this might be overlooked in an isolated pediatric practice, it would more readily emerge in the kind of collaboration described here. Still another example of the potential of such group work is our plan to periodically retrieve all records of patients with learning disorder to review the efficacy of our evaluation program.

For those cases in which there was a recommendation for further therapy outside the service, there may have been a disruption in the kind of continuity we were trying to achieve. Although the Yale service does not offer psychiatric therapy at this time, other HMO-type plans do. The initial benefit level in any program is often based upon the experience of others as well as on actuarial predictions. However, analogous programs have been very few, and predictions have necessarily been based on the experience of groups that did not have such comprehensive medical care available to them as ours does.

Even more significant, however, is the fact that predictions of utilization have been based on a view of psychiatry as a therapeutic specialty—and to a great extent, it *has* been this. Secondary prevention (early diagnosis and treatment) has been achieved only sporadically and efforts to move toward primary prevention (elimination of the causes of disorders) have been largely disappointing. The community mental health center represents but the latest of these efforts toward prevention; the results are not yet conclusive.

There is no doubt that in our first year of pediatric-child psychiatry collaboration in the Yale Health Service we were able to operate on a secondary preventive level to a greater extent than any of us had done previously in our individual work. For the pediatrician it was not only easier to act on psychological problems but harder to ignore them. Cases often came under review and discussion well before distressing symptomatology summoned the attention of parents or school. However, what was even more exciting was the recognition of the potential of a pediatric-child psychiatry team to work in a primary preventive mode. If the principles of psychodynamic development have validity in psychiatry, it stands to reason that immediate response to the specific needs of the developing child and his family should prevent serious psychological distress in many instances. The pediatrician is "on the scene" from the mother's pregnancy onward and, provided with the structure and support of the kind of collaboration described here, should be able to oversee the child's development, thereby providing continuous and informed guidance and (when necessary) early intervention. Although the long-term nature of such an endeavor prevents immediate answers, both the number of children seen in a group practice and the facilities for collecting information in this kind of setting provide the feedback needed to guide these efforts.

If such an attempt at primary prevention is even partly successful it should eventually be reflected in a lower rate of utilization of psychological treatment. Earlier predictions would have to be revised and more comprehensive psychiatric coverage could be offered. Furthermore, if such collaboration is successful, it can provide a model for other interdisciplinary work (as it has in our plan) and

will be a major step toward the realization of the goal of comprehensive health care.

Questions of the Month

Directions: Each of the questions or incomplete statements below is followed by four or five suggested answers or completions. Select the *one* that is BEST in each case.

Question 1 Under usual clinical conditions, if the Rorschach indicates a greater degree of psychological disturbance than is apparent in the clinical interview of an adult patient, the most likely reason is that the

(A) Rorschach test has very limited validity for assessing psychopathology
(B) patient is intelligent and skilled at concealing information
(C) Rorschach test taps a layer of functioning obscured by ego defenses
(D) interview is consistently less valid than the Rorschach as a diagnostic procedure
(E) patient is suffering from pseudoneurotic schizophrenia

Question 2 For which woman would the risk of bearing a child with Down's syndrome be greatest?

(A) A woman of any childbearing age who is a translocation carrier
(B) A woman who is not a translocation carrier but who has a child with Down's syndrome
(C) A primagravida under 20 years old
(D) A 35-year-old woman with four children, one of whom has Down's syndrome
(E) A primagravida over 45 years old

Changing Human Service Delivery Systems: Their Influences on Psychiatric Training

BY ROBERT S. DANIELS, M.D.

Human service delivery systems are the focus of problems and controversy in 1973. The systems that pertain to mental health and illness have incorporated many of the innovations in organization, delivery, and administration that appeared in the 1950s and 1960s. The author argues that these may evolve into arrangements in which mental health delivery is either separate (as in the community mental health center) or integrated in varying degrees with other health care systems and that the choice of arrangements will affect the training of psychiatrists.

DURING THE 1970s this country will struggle with complex social problems as it strives for a better quality of life for its entire population. The human services—educational, health, legal, and social services—have key contributions to make. These services, often organized to promote the growth, development, and adaptation of individuals, families, and communities, have more often served only to assist people who are already in serious difficulty. In this respect, these services are judged by many to be inadequate. Reorganization, innovation, and experimentation with careful evaluation are indicated.

The problems that are common to most human service systems include: 1) professionals who seem more interested in maintaining their methods and standards than in altering their methods of service delivery to respond to client need; 2) bureaucracies that also seem more interested in sustaining themselves and their employees than in improving client services; 3) service systems that resist experimentation with new methods of human service delivery and new types of staff; 4) a public that has been unwilling to finance services at an adequate level (too many clients and too few services); 5) the lack of an effective, comprehensive system of service delivery; and 6) data that do not reveal which methods lead to what outcomes for which individuals and which communities.

The treatment of mental illness reflected many of these problems from the late 1940s to the 1960s. Revisions that were designed to correct some of these difficulties and deficiencies were sometimes consciously thought out, planned, executed, and evaluated; more often, however, they were the result of situations in which improvisations were necessary and a crisis was turned into a service delivery advantage. These changes included the multidisciplinary team, the therapeutic community, the "open door," a decrease in the size of institutions, early treatment close to the home community, psychiatric units in community hospitals, improved aftercare, and the use of new and different sources of manpower. The psychological sciences and services also became potential bridges among many services. They supplemented and complemented the medical, social, educational, legal, and other human services. These advances were amplified or initiated by improved drugs, a more sensitive and more involved community, and a more optimistic view of mental illness. An attempt was made to bring these strengths together and systematize them through the community mental health center. Although it added little that was new, this movement synthesized a mental illness service delivery system from the advances of the 1940s and 1950s.

Currently, the planner and deliverer of mental health and illness services needs to consider several complex questions. When should mental health or illness delivery systems be separated organizationally? When should they be a part of other systems? If they are to be combined, which system should be primary? What are the implications of various arrangements for the careers of psychiatrists and for psychiatric residency training? Is there likely to be a "best" way of accomplishing improved and more effective service? Or will there be multiple organizational methods based on consumer, public, and professional choice or local conditions?

Part of the problem with which mental health professionals struggle is the absence of a feasible national policy for an organizational or financial structure for treating mental illness, for treating physical illness, or for providing social services. This lack of a national policy results in a lack of clarity about future developments. Although the community mental health system format has now been in the process of formation and implementation for almost ten years, often the local and federal financial support to promote optimal and rapid development has not come forth. In fact, there has been almost no new funding in the last several years and it is unclear whether Congress, the federal administration, the public, and the bulk of professionals conceive of this method of service organization as really feasible in our present society. There is some current evidence that the nation is progressing toward policy formation in health and welfare services, although neither the organizational nor financial issues are yet settled. It is, however, unclear

Dr. Daniels is Professor and Director, Department of Psychiatry, University of Cincinnati, 234 Goodman St., Cincinnati, Ohio 45229.

whether services for the mentally ill will be included and, if they are included, what the quantity and quality of that inclusion will be.

No one has answers. It seems unlikely that there will be a single answer in a society that supports pluralistic systems of human service and consumer choice. The ultimate arrangements may vary according to the characteristics of the population, the geographic location, the population distribution, the professionals and institutions available, and, most of all, personal, client, and community choice.

The possibilities that must be considered are the community mental health center model (primarily a separatist model), a model in which mental illness services are integrated with other health and illness services, a model in which mental illness services are a part of other human service systems, and a multiservice model.

THE HEALTH AND ILLNESS SERVICE DELIVERY SYSTEM

Psychiatry has historically been a specialty within medicine. As such, it has been a potential or actual collaborator with other medical disciplines. From a relatively minor and unimportant position 30 years ago, psychiatry has increased in importance; it is now the specialty with the third largest number of practitioners and is now a recognized presence in most communities, medical practices, hospitals, and medical schools. These changes have not been accomplished easily; frequently psychiatry has been regarded by its medical colleagues as unscientific or unimportant. Further, the rest of medicine has envied psychiatry's more generous share of public training and research money. It is not surprising that psychiatry, discouraged by the attitudes and behaviors of the rest of medicine and encouraged by special public funding, has tended to establish its own systems of care and education or that there have been tendencies to separate the mental illness service system from medical care systems. The community mental health delivery system may have been a necessary step in the development of improved service systems for the treatment of mental illness. However, is it the best system? Or, if psychiatry and other services for the mentally ill received their appropriate support within a medical care system, might that be a better arrangement?

Currently, the medical service delivery system is the center of a good deal of national attention because of major organizational and financial difficulties. The major symptoms are: 1) inadequate outpatient medical care in terms of the number and types of personnel and the characteristics of the service delivery system; 2) uneven distribution of care in terms of geography, economics, and race; 3) a two-level system of finance in which the fee-for-service system is usually of higher quality; 4) inadequate financing for poverty and near-poverty populations; 5) a shortage of suitable preventive, rehabilitative, and sociopsychological services; 6) insufficient physician manpower and professional and institutional resistance to using the services of paraprofessionals; and 7) a fragmented system that the patient finds difficult to understand and manage.

Several approaches are currently under consideration by local, state, and federal governments to remedy this situation (1–3). They include: 1) the reorganization of medical care into closed systems in which comprehensive services are available from a single organization (e.g., health care corporations, health maintenance organizations, physician foundations) and 2) universal or national health insurance. These approaches are often combined in proposals for a closed panel group practice with prepaid capitation financing that delivers comprehensive services. The existing models that most closely approach this ideal are the Kaiser-Permanente plans, some union-sponsored or union-owned health plans, and certain physician-foundations or corporations.

The ownership and governance of such plans may be invested in communities, groups of consumers, unions, businesses, physicians, or hospitals. These ownership models may include or exclude physicians. Physicians may be salaried by the corporation or they may be separately incorporated and negotiate with the medical care corporation to provide services under contract arrangements subject to periodic review. The site of practice is often a health center and the physician on the staff may represent a number of specialties and general practice. The size of the population that can be best served is a controversial issue, but most experienced observers believe that 50,000 to 100,000 people is optimal.

Under these systems, ambulatory care could be delivered from a health center in which there would also be substantial preventive and outreach activities. They would be tied through ownership or contract arrangements to specialty outpatient services, hospitals, nursing homes, and rehabilitation services. It is hoped that this would provide ease of access, established criteria of eligibility, a common record, and smooth patient flow, with a minimum of the usual staff, organizational, and bureaucratic impediments.

Such plans as the prepayment capitation plans hope to distribute costs equitably and to stabilize the expense to the consumer and the public. Current evidence suggests that this method of service organization and financing decreases the use of the hospital (patients are hospitalized only 60 percent to 90 percent as often as in other systems with similar populations) and the frequency of the use of expensive services, particularly surgery. Other potential advantages are that the system can be manageable and responsive, that evaluative data can be gathered, and that the different elements can be varied and the results systematically appraised.

The place of mental illness services within such systems of care has remained unclear. Although the possibility of realistically including mental health services has been demonstrated (4–6), Congress, the Administration, and, most important, the public have not yet demanded their inclusion. The reason usually given is the possible expense—too many people requesting too much treatment. This belief is based, I believe, on the fantasy that

psychoanalysis or long-term intensive psychotherapy is the best treatment for everyone. In fact our experience suggests that most individuals and families want and benefit most from brief services within a brief time period. The exclusion of mental illness services from such plans may also be an expression of fear or prejudice.

What then might we anticipate under the best circumstances from the new health proposals?

1. The current system would evolve into something different; revolution now would only be destructive.
2. The minimum benefit package would be specific and clear and easily understood by consumers and providers.
3. The benefit package would include mental illness services. At a minimum this benefit package might include emergency services, up to 20 outpatient visits a year, general hospital services (including day care) for up to 30 days a year, consultation and education for other members of the medical and social service teams, and outreach and prevention services.
4. Further evolution of a benefit package should be possible with the expansion of benefits after the initial experiences.
5. The pluralism of our current system should continue. Any new system must be able to adapt to combinations of public and private insurance, or of both prepaid and fee-for-service mechanisms.
6. There should be compulsory coverage for the entire population.
7. Quality control and evaluation mechanisms should be built in from the outset.

EDUCATIONAL, LEGAL, AND SOCIAL SERVICE DELIVERY SYSTEMS

The evidence is that service delivery in other human service systems is no better than in the medical delivery system. The educational, legal, and social service delivery systems are occasionally excellent; more often they are plagued by client overload and show limited evidence of success. The problems seem similar to those found in medical service delivery: the bureaucracies are large, the professionals are bound to traditional techniques, the systems are unresponsive to consumer needs, the problems presented by users are overwhelming, the service system is underfinanced and is fragmented—not only within, but also in its connections to other service systems.

In each of these delivery systems mental health and illness services have an important role to play. These services are often provided in primary sites, where a considerable amount of preventive mental health work might be accomplished. Early intervention by professionals and nonprofessionals from other systems may obviate the later need for mental illness services. It is therefore the educator, the minister, the judge, the policeman, the social worker, and the physician who are likely to be the early contacts during the first symptoms of maladaption. These people are more often concerned with growth and development, how the individual and his family can be aided to develop their maximum growth and potential. These professionals often have not been specifically trained to be sensitive to the emotional needs of their clients or to deliver effective mental health service. Also, the other services are often unwilling or unable to finance the mental health and illness services that would be necessary to promote and optimize their own basic services.

Although mental health personnel within these other systems (especially psychologists and social workers) have occasionally provided direct service as actual members of the system, more frequently they have served as consultants—sometimes with individual clients or families, sometimes concerning classes of client problems, the training of personnel, or the functioning or politics of the agency. If properly utilized, psychiatrists can be useful as consultants and educators, contributing to policy formation and the improved functioning of the agency and its personnel as well as providing direct services to clients.

Another alternative exists, although it has been less frequently used in educational, legal, and social services. Mental health and illness services may be an essential and integral part of the service; agency personnel and mental health professionals may collaborate to provide the needed services. In the educational system this has taken the form of pilot projects in public schools or, in private settings, special procedures for entire schools. In the legal system such arrangements have occasionally occurred in particular courts, probation systems, or prisons. In the social service delivery system, a strong mental health and illness component is found more frequently. However, in this system (e.g., welfare or social agencies) the overwhelming demand for service is such that intervention for mental health or illness may be lost or compromised.

For the foreseeable future, it seems likely that the psychiatrist will work primarily as a consultant in the educational, legal, and social service delivery systems. To do this, he must be knowledgeable about individual, family, and small group behavior and understand both normal development and abnormal behavior. While his diagnostic and therapeutic skills may not be used often in direct service, they are essential underpinnings to his other services to the agency as an educator and consultant. The presence of these skills alone does not, however, make the psychiatrist an effective consultant. He must also be able to evaluate the agency's organization, administration, finance, and personnel. He must have some understanding of social systems and social fields and be able to conceptualize the problems and processes, plan and execute the interventions, appraise their effects, and adjust and respond accordingly. This process is fully as complex as individual, small group, or family treatment and requires training sequences that assist the psychiatric trainee to develop the necessary skills and competences.

SEPARATE VERSUS INTEGRATED SERVICES

The mental illness service system is confronted with a

complicated set of opportunities that require it to decide in a particular locale and under particular circumstances whether it will become or remain a separate mental illness delivery system, as in most community mental health centers, or attempt to integrate its services with other services. People's needs (individual, family, or community) are rarely satisfied within the framework of a single discipline or service system. Rather, they are multiple and span several areas of knowledge, involving several types of professionals and service systems. For the client every transfer from one system to another and every entry into a new one is a difficult process. The impediments include different locations, records, rules of eligibility, intake procedures, definitions of priorities and objectives, contacts with new people, and too often limited or poor communication among the professionals involved. If the new service is in a new location and the client has problems in getting there, the attrition rate is very high. Although we often speak of the client's lack of motivation, we rarely consider how difficult we make the processes that lead to service. Such problems are also often accentuated by cultural, racial, and economic differences between the servers and the served. Recent attempts to create a multiple service center under a single roof or under the auspices of a single organization recognize that fact (7). In reality, though, such multiple service centers are difficult to create and difficult to operate.

The alternative of entirely separate systems has some obvious strengths in this society. Such a system creates its own organizational, administrative, and political power base. It acquires its own resources by being its own advocate. It creates its own priorities through the agreement of its board, staff, and consumers. This authority and control offer greater flexibility if they are appropriately used. From this base it is then possible to cooperate with other systems to provide jointly sponsored services that may include a significant component for the treatment of mental illness or contributions that might promote mental health. The particular and separate treatment services we have developed in office, clinic, and hospital settings usually fit this model. The combination of services within a catchment area that has been synthesized into the community mental health center also corresponds to this model.

The challenges of such developments to evaluation and research are striking. We must learn more about which methods and procedures lead to what results. What are the significant variables and how can they be evaluated? What data could lead to rational decisions about the quantity and quality of services and expenditures? With increasing shortages of resources we must find a more rational way of approaching decisions or we will continue to squander scarce resources when there are citizens in very great need.

THE IMPACT OF NEW SERVICE DELIVERY SYSTEMS ON PSYCHIATRIC RESIDENCY TRAINING

The most important single issue in residency training is bringing together the trainee, the patient, and the teacher within an effective delivery system for the care of mental illness. In the past we have tended to accomplish the first of these conditions, bringing together trainees, patients, and teachers, without much difficulty. We have been less successful in establishing and participating in effective delivery systems. Usually we have presented opportunities for inpatient, outpatient, emergency, consultation, and related services in block rotations to the trainee. Although some progress has been made in psychiatric education, there continue to be great deficiencies (8, 9). There has been the possibility of selecting or rejecting whomever you please. There has been a mystique surrounding the selection of the "good" patient. There are frequently impediments among services within the same institution or department; each clinical service is insular and is under no obligation to accept any particular patient or group of patients, nor is there any real organizational encouragement to collaborate. There are often waiting lists and repeated intake and diagnostic interviews. These problems have resulted in a skewed view for the trainee of the services that are offered and a perpetuation of the fragmentation that the institution and professionals support and the consumers endure.

In many places, since services are delivered chiefly by the trainee, some of these artificial impediments and constraints are designed to protect the trainee and his training from too-high expectations of service. In most areas of this country we have not been willing to support our mental illness service systems, particularly those for the poor and near poor, at a level at which the trainee's presence is not absolutely essential. So long as this condition prevails, it is unlikely that the trainee will be educated in an ideal system or that he will have the experience of functioning within a comprehensive integrated system with both its difficulties and its advantages. Although the ideal may not be attainable, it is shortsighted to ignore the deficiencies in our current system and to foster training in which the trainee never confronts some of the real problems of mental illness service delivery.

Most psychiatric residency training programs are so deeply entangled in the problems of training, service expectation, and public financial support that they cannot undertake a new program without partially extricating themselves from the old. They fear the loss of their sources of financial support if they fail temporarily to meet the expectations of the public for continuing service.

The most common new pattern of service delivery is likely to be that of the health maintenance organization or health care corporation. Whether educational institutions should own these new service delivery systems is unclear at the moment. Most of the past examples of university ownership have not produced sensitive, responsive, or responsible service delivery. Clinical service needs are likely to be subordinated to so-called educational needs, with the result that both the clients' and trainees' needs are compromised.

Some new patterns of ownership are currently being explored. The most promising of these is ownership and governance by groups of consumers. This arrangement

places the educational institution in a contract relationship with the service organization. Each has authority and responsibility and the negotiations are conducted between equals. Each also has the option to leave the contract arrangement if it is not satisfactory. The risks for both are higher, but the likelihood of better service and training is probably substantially greater. The educational institution may accomplish its educational and research goals and experiment with and improve human service delivery. Other benefits could include more realistic cost allocation, less confusion about objectives, and a better opportunity to determine whether objectives are accomplished or not.

If there are to be several models of human service delivery, then there should be exposure to more than one model during training. For the time being, the integrated comprehensive mental illness service model currently known as the community mental health center is probably the best. This system consists of comprehensive mental illness treatment services integrated into a single system that has the responsibility for a given population and allows no rejection or export of a patient to other systems. This system should become the major site of training.

Training should also occur in the health care corporation, the health maintenance organization, and the educational, legal, and social service systems. In addition to direct service responsibility for individuals, small groups, and families, the trainee should receive supervised training in consulting about individual problems, classes of problems, agency functioning, administrative functioning, and budget. He should have the opportunity to sharpen his skills as a teacher so that he will be prepared to teach and to learn from a variety of other professionals and the public. More emphasis should be placed on administrative training, individual service, and the evaluation of the services of partial and whole systems. Only with this variety of learning opportunities will the trainee be ready for the complicated uncertainty that lies ahead.

A few predictions may be in order:

1. Treatment of individuals, small groups, and families will continue to be the psychiatrist's major contribution.

2. It is his understanding, his analysis, and his capacity to change human behavior that will support these activities.

3. In the future less time will be spent in direct treatment and more in consulting, supervising, and educating those who will engage in direct treatment.

4. Some of these people will be other mental illness technicians and professionals, but many service deliverers will be in other human service systems.

5. One of these other human service systems with which the psychiatrist will be deeply involved will be the health care corporation or the health maintenance organization.

6. If services for the mentally ill or the emotionally maladaptive are included in a national health and illness insurance benefit package, this change in financing, probably accompanied by changes in the organization of services, will profoundly affect the site and the type of the psychiatrist's work.

7. Involvement with educational, legal, and social services will be more frequent and more intense for most psychiatrists in the future. Many psychiatrists will be involved to some degree, and a few psychiatrists will be profoundly involved.

Our task, then, is to prepare our trainees in educational programs that encourage their participation in and learning about the more likely, more common, and more effective human service systems. They also must be flexible enough to alter their activities and sites of practice with changes in human service organization and financing.

Answers to Questions of the Month

Page 1231. Question 1: C; Question 2: A.

On the Stresses of Community Psychiatry, and Helping Residents To Survive Them

BY ANDREW P. MORRISON, M.D., MILES F. SHORE, M.D., AND JERALD GROBMAN, M.D.

The authors underscore the major themes that challenge the resident who moves into community work from his initial experience as an individual therapist. The resident must be able to change, especially in terms of his own role expectations, to expand his repertoire of professional techniques, and to move from his former relatively passive stance to a new role in which he becomes more active. The supervisor should be ready to guide the resident in his work and be sensitive to his anxieties.

WITH THE COMMUNITY psychiatry movement of the 1960s, the relationship between service commitment and training orientation in psychiatric centers has come under scrutiny. If community psychiatry is to offer a major new theoretical model, with the community mental health center as its instrument, how can psychiatric training centers with a traditional viewpoint adapt to the demands of this movement and train potential leaders in the techniques required by community work? Early there developed schisms between the community psychiatrist and the psychoanalyst, and between intrapsychically and socially oriented factions (among other competing groups). More recently, however, several departments have moved toward integrating community concepts and experiences into general psychiatric training in an attempt to break down the barriers between community mental health and the rest of psychiatry (1–5).

The program from which the present observations were made is still evolving within a department that aims at reducing the polarization between community-oriented and psychoanalytically oriented psychiatry. The Tufts Mental Health Center is part of the Massachusetts system of community mental health centers; it consists of an affiliation of 17 agencies already existing in the South Boston-North Dorchester communities. At the same time it is an integral part of the training activities of the Tufts Department of Psychiatry, a dynamically oriented training center of Tufts Medical School and the New England Medical Center.

Some of the problems that psychiatric residents encounter as they move from the protection and status of the consulting room into the activity-oriented marketplace of the community will be considered here.

This paper is based on a panel discussion at the 125th annual meeting of the American Psychiatric Association, Dallas, Tex., May 1–5, 1972.

The authors are with the Department of Psychiatry, Tufts University School of Medicine, Boston, Mass., where Dr. Morrison is Assistant Professor, Dr. Shore is Professor and Associate Dean for Community Affairs, and Dr. Grobman is Assistant Clinical Professor. THE NEED FOR TRAINING IN COMMUNITY PSYCHIATRY

From an institutional point of view, ideological values and funding necessities both support a shift toward delivery of mental health services at the neighborhood level. In order to prepare staff to work in these new programs, training in community mental health is becoming a significant part of residency training across the country; thus there is increasing emphasis upon crisis intervention, brief psychotherapy, outreach programs, aftercare, home visits, and even community organization and political action.

Also, the demands and needs of students entering residency training are shifting. In general, medical students during the late 60s and early 70s grew up in an atmosphere of activism, social commitment, and idealism that was not experienced by those of us who came before. A major shift in the professional goals of residents across the country has occurred, moving from an emphasis on exclusively psychotherapeutic private practice to the inclusion of more active, community-oriented roles. Part of this shift has led to demands by individual residents for more autonomy in determining the course of their training. Struggles between residents and their therapy supervisors reflect in part a desire to move out from under the thumb of their teachers and to become more actively involved in the community surrounding the training center. This shift, then, is part of a greater interest in and demand for training in the techniques of community psychiatry from some residents. Other residents, however, are anxious and resist deep community involvement.

PROBLEMS ENCOUNTERED IN COMMUNITY INVOLVEMENT WITHIN A GENERAL RESIDENCY PROGRAM

The problems enumerated in the following sections refer specifically to psychiatric residents, but obviously the same stresses may also apply to other mental health professionals and workers. These problems will be formulated in terms of specific anxiety-provoking stimuli and occasional responses to them that may be determined by the character styles of the residents themselves. The "culture shock" encountered from working in a community setting leads not infrequently to regressive trends, while

at other times it merely reinforces the disinclination of some residents to participate in community mental health. Other residents, of course, readily accept the challenges of community psychiatry.

1. From the Safety of the Office to the Dangers of the Community

In most training programs the resident is introduced to the central task of individual psychotherapy in a quiet office. In general, this office is his "turf," a haven for him alone to explore the intricacies of a patient's inner life. Here is seclusion, a place in which to conceptualize and feel, a potential retreat from the demands of patients, supervisors, and administrators.

Upon entering the community, the resident is stripped of this haven and must see people in busy, public, uncomfortable surroundings—the open marketplace. The setting is no longer of his choosing but is "theirs"—the alien turf of the community, where he is a guest. No longer can the resident sit back and wait for his patient to knock at his office door. Instead, he must initiate contact with people, in their domain, and with unclear goals. This change is, we believe, one of the important and underrecognized anxieties and sources of alienation in beginning community work (6).

These settings may include the large state hospital with its barren wards and disturbing inmates, the living room in home visits made to the families of patients, street consultations with adolescents and gangs, discussions with community leaders in cars while driving to a meeting, etc. This experience, it seems to us, leads not infrequently to a projection of the resident's own hostility at being ejected from his safe office. In this projection the responsibility is shifted from the resident's feelings on finding himself in an alien setting to questions of "treatability" of the patient. It is not the fact that the resident is frightened to be in the living room of a lower-class home that makes it difficult for him to treat patients, but rather that the patient is too sick or "too primitive."

2. From Receptivity to Activity

There are several facets to this particular point. Not only is the resident stripped of the protection of the office, but the comfort of having a patient request help is also gone. Much of community psychiatry is involved not with patients but with populations at risk, consumers, and ordinary citizens. To a certain degree, beginning residents learn to define themselves in terms of their role as "not patient" or helper, and for this self-definition the presence of a patient is essential. When this role does not apply, as is the case in much community work, psychiatric residents are confronted with a role diffusion of their own. Also, patients whom the resident is asked to see may differ sharply from those seen in clinics or on inpatient services. He may be confronted with a wildly aggressive family; the whole unit may be defined as the patient. The "patient" may be a dissatisfied group of community residents demonstrating for better health care.

These are situations with which the supervisor, to whom the resident turns in fright, may himself be unfamiliar. The supervisor can provide support, but the resident himself must frequently muddle through the situation as best he can, relying on his own judgment and developing expertise as he goes along. The need for self-reliance provokes considerable anxiety in the beginning resident, but it may also help him free himself from the infantilizing quality of supervisory relationships. The resident may choose to respond to the patient in a way other than as therapist. He may find a conflict between the role of clinician and consultant and may choose to help other workers serve as primary care givers. This role of consultant is new to the beginning psychotherapist.

Related to the switch in orientations necessitated by community psychiatric work is the matter of professional identity. There is frequently a conflict between seeing oneself as a screen reflecting the patient's projections and using oneself as a reactive person interacting with other real people in the community. As a function of supervision that necessarily teaches beginning residents to be more objective, scientific, and not quite so "giving" to their patients as they would ordinarily be, they learn a professional persona that is detached and aloof from patients. The neophyte resident may become like the familiar caricature of a psychiatrist, who responds to questions with more questions rather than with appropriate answers.

In contrast, the resident entering the community must learn to use his psychiatric skills with a persona that is more like ordinary social behavior. He is called upon to be a "regular guy" who meets agency staff and consumers openly and with respect. Can he be a real person and at the same time maintain his identity as a psychiatrist? The community experience can enhance a maturing process in which the resident learns to be real, available, and open in the formation of working alliances with community staff and patients alike.

However, this challenge can also cause turmoil in the beginning therapist. Not only is he confronted with the absence of the "patient" role, but his role definition as physician is undermined. He is demoted from the leadership position familiar in the hospital team, inherent in the primacy of the medical model. As psychiatric therapist, he determined the course of treatment and medication for his patients. In the community, however, he must interact as a peer with people from various professional backgrounds and frequently must take directions from a superior who lacks medical training—the agency director or community leader. This new set of role relationships is a blow to the resident's hard-earned status and self-esteem; residents' reactions to this loss vary widely, but it is a challenge to them all.

3. Role Conflicts in the Community

In this context we refer to the tendency, implied earlier, toward "either-or" thinking with regard to professional commitments. Because of the difficulty in learning intensive individual psychotherapy, many residents view psychoanalytic training as the pinnacle of their professional career. Others perceive the commitment to dy-

namic psychiatry of analytically oriented teachers and adopt what they consider to be an opposite, action-oriented community approach. These orientations tend to become polarized, with residents feeling that they have to choose between them. Thus if the resident sees himself heading toward an analytic career, he is sometimes anxious about feeling an interest in participating in community events. This problem can be minimized if a department's attitude is respectful of both orientations, emphasizing that they are not mutually exclusive. In the Tufts program, for instance, the fact that many of the psychiatrists working in community mental health are also psychoanalysts or analytic candidates demonstrates that one can at the same time be psychoanalytically oriented and work in the community.

However, related to the role conflicts that residents feel with regard to these orientations is the ever-present subtle devaluation of a community psychiatric orientation by therapists who are not at the same time involved in community work. Thus supervisors of individual therapy may ask, "What does the community psychiatrist really do?" or they may state, "I guess if one is uncomfortable sitting with patients and sharing their feelings, one can always do community work." This devaluation by people esteemed for their clinical abilities establishes professional priorities for the resident and makes it difficult for him to view community work with the same commitment as his more traditional therapeutic endeavors.

4. The Lack of Structure

With regard to time to be spent in the community, the work task to be established, and the identity of consumers with whom to interact, the resident is confronted with a lack of structure and defined expectations very different from his experience in doing psychotherapy. In contrast to the office appointments at a set hour, the resident may be asked to enter a neighborhood, contact agencies and find useful ways to interact with them, and meet people at unspecified times. The consumers do not have set expectations of the resident, and relationships must develop out of mutual exploration and discussion to establish shared goals. The resident cannot turn to his supervisor to be told what he should do, for frequently it is not clear which intervention or approach is the most effective for a given community situation. As an example of this turmoil and lack of structure, one resident entered a tumultuous situation in an agency just at the time that a generalized staff rebellion against the agency leader was in process. There was tremendous anger and confusion among the staff of the agency, and the resident was pulled in all directions to take a stand on his loyalties. In supervision, he confided that he did not even know what his task in the agency was supposed to be, let alone which groups he was to align himself with.

This chaos offers the opportunity for a real mastering experience, in which the resident can attempt to structure and understand both his task and his role within the agency. Intellectualization and other organizing defenses can be used in the mastery of an unstructured situation. On the other hand, some residents respond to the lack of structure by withdrawal and avoidance, retreating to a setting in which they feel more comfortable. Residents tend to reestablish well-integrated activities in alien surroundings in an attempt to bring familiarity to their task. An example of this tendency is a resident who elects to evaluate and treat patients at the new setting or agency. He might alter the therapeutic modalities that he offers (e.g., beginning to do brief psychotherapy), but it is psychotherapy nonetheless.

5. Community Rejection and Apathy

A major source of anxiety is the not infrequent response of disinterest and/or open hostility of community groups when the resident comes to offer his services. Used to gratitude, deference, or at least respect from his patients, the resident frequently is faced with angry, demanding citizens who criticize him or his profession for ignoring their needs or shun him for representing a discipline that frightens or alarms them. Such a response strikes a blow at professional pride and is the source of the anger and withdrawal of many residents in the community. An example of this response occurred when one resident, with the selfless feeling that he was offering his services to the poor, was interviewed by a citizens' committee on professional hiring for a ghetto health project where he wished to work for one day a week. The resident's motivations were challenged, he was called a racist and a do-gooder, and the committee finally rejected him for work in its center.

In our experience, some residents respond to such hostility in the community by recoiling with the shock of injured pride—the feeling of "Don't they realize that I am here to help them?" The resident may become angry and resentful in turn, either intellectualizing his experience (sometimes in a condescending manner) or withdrawing to avoid repetition of the situation. This anger is frequently a response to his being deposed from a position of control and relegated to being just another team member.

One example of the response to apathy is that of a resident who attempted to establish mental health consultation with the faculty and staff of a local high school, but who was perpetually confronted with excuses, unreturned telephone calls, failure of some faculty and staff to show up for scheduled meetings, etc. Certainly this experience is common to any worker actively engaged in trying to establish a mental health program. The response pattern includes that of injured self-esteem. However, rather than the anger with which many residents respond to community hostility, in the case of apathy one frequent response is that of depression and withdrawal. The resident wonders what he is doing wrong, why he is not being accepted for what he has to offer. He experiences considerable self-doubt and, occasionally, the depression that can accompany such a drop in self-esteem.

6. Excessive Expectations

In this last source of anxiety, residents initially place an excessively high demand on themselves to produce meaningful change. They may hope to restructure an

agency, overhaul society, or even change educational systems, as well as providing mental health aid to citizens. One resident, for instance, began to meet with a group of teachers in a local parochial school. Not only did he hope to teach them techniques of helping their students, but he also wanted to impart concepts of family dynamics and progressive teaching methods. Obviously his goals were unrealistic; it did not take long for the teachers to set him straight, since attendance quickly dwindled.

In attempting to meet these excessive expectations, the resident is frequently shocked by the limited change he can effect. He may intellectualize his distress at falling short of his own expectations, but he usually becomes anxious, and having failed to meet his own goals, he withdraws from the field.

HELPFUL HINTS FOR EFFECTIVE SURVIVAL

Recognizing that these stresses are inevitable and can never be totally eliminated, but must be weathered and gone through as part of professional development, we turn now to considerations of what can be helpful to the residents in mastering them. These suggestions will not be dramatically new to supervisors of psychiatric residents, and it will be seen that in many ways the supervisory task is similar to that of clinical supervision for new therapists. In fact, it is the familiarity of this supervisory relationship that gives the instructor a toehold in helping the resident to master his anxiety in this new professional endeavor.

Structuring

The supervisor must realize that the resident has very few guidelines or preconceptions of what his task in the community should be. He should thus be encouraged and assisted in defining one or more specific tasks with regard to agencies or a segment of the community with which he is going to interact. In order to assist the resident in doing this, of course, the supervisor must be familiar with the scope and tasks of community psychiatry and the range of possibilities open to the resident. The supervisor must know the community in order to be realistic in this task.

The process of structuring should be a mutually thoughtful exploration of possibilities, and the resident's own preference, fears, and feelings about his limitations should be fully considered in arriving at a project for his community work. Also, the need of the community or agency and the service commitments of the mental health program must be accounted for in helping the resident to define and structure his own task. At the Tufts Mental Health Center we have found that an important ingredient of the community experience, after the resident has had time to explore the range of options open to him, has been his own participation in structuring his work.

Conceptualizing

This relates very closely to the structuring factor just discussed. Here, we help the residents to step back from their immediate community experience, to look at the various issues in the task being required of them, and to formulate their plans, much as a supervisor helps a therapist to formulate his patient's needs and treatment goals. Basically, we refer here to utilization of mature intellectual skills to master a potentially chaotic experience. For the past two years at the Tufts Mental Health Center we have offered an introductory seminar for residents prior to their community experience, covering such areas as crisis intervention, brief psychotherapy, mental health consultation, and home visiting.

Support

The instructor of the beginning resident in community mental health must be aware of the stresses that the work involves (enumerated earlier) and willing to intervene supportively to share his trainee's anxieties. Of course, this is also true of clinical supervision, but the diffuseness of the task and the fact that the supervisor will not always have dealt with similar community situations himself makes the emphasis somewhat different. On the other hand, as in the experience from psychotherapy, some anxiety is necessary in order to motivate growth and change.

This inherent dilemma requires sensitivity to the resident's potential for being overwhelmed by anxiety and the supervisor's attention to cues that this may be occurring. Supervisors should make themselves available for night consultations to their residents, since emergencies may arise in the community at any hour. The instructor must also empathize with the resident's anxiety in situations that might normally seem trivial, e.g., meeting with a group of angry adolescents, approaching a meeting with a school principal to set up consultation with teachers, etc. The supervisor must be willing to switch into a clinical framework when emergency cases arise in the community and be able to share his own confusion or lack of knowledge when this is indicated.

The supportive function, then, represents a willingness to accept the resident's confusion in his new task, to provide a model of open humanness that he can emulate, and to share responsibility appropriately. This may help the resident to decrease his excessive expectations and hence to modify his guilt.

Psychiatric Commitment to Principles of Community Mental Health

In order to help the resident master his stresses in community work, the staff supervisor *must* be respectful of the community experience. Very often, as noted earlier, there is an unwritten message in analytically oriented departments of psychiatry relegating the community psychiatric work to second- or third-order importance. If the supervisor is unable to oppose such downgrading, how can the resident do otherwise? Thus a department committed to training in community mental health must also value community activities. The supervisor in community psychiatry must be able to help the resident to place in perspective some of the professional negativism to which he will be exposed, and ultimately—if community training is to be effective—there must be a cadre of flexible

staff members who serve as role models of equal status to teachers committed exclusively to intensive individual psychotherapy.

SUMMARY AND CONCLUSIONS

We have not attempted to present the ultimate word on how to help residents survive their community psychiatry experience. Rather, we have tried to underscore the major themes that challenge the resident who moves into community work from his initial experience as an individual therapist. We have presented these problems from the viewpoint of the resident and have related some of the more frequent anxiety-provoking stimuli to typical responses in terms of character styles of the residents.

We have an obligation to supervise and support the resident as he meets the challenge of community mental health, and in the process we are asking that same resident to *grow* as a mental health professional. In fact, we are asking the resident to *change*, especially in terms of his own role expectations. As the therapist requests and stimulates change from his patient, so too must training in community mental health require that the resident expand his repertoire of professional techniques. We ask that he be able to move out of the newly learned, relatively passive stance of the psychotherapist waiting in his office for a patient who requests help to a new role in which he becomes more active, involved in change, reaching out as an advocate of programs, techniques, and activities.

In effect, we are often asking him to add some of the skills of the salesman in presenting helping techniques to the consumer, who may not know of the mental health professional's skills or abilities (7). He must be willing to meet the challenges of lack of interest and resistance that he will find in the community and to take on what may be for him the new role of teacher. We ask him to step out of a role that emphasizes patienthood and the medical model and to interact as colleague, student, teacher, and even adversary. Finally, he must be willing and able not only to use the professional, distancing skills that he has learned in the initial experience with psychotherapy, but to integrate into a comfortable style personal, open skills of human relations that he has practiced in other settings since childhood.

Addicted Viet Nam Veterans: A Comparison of Self-Referred and System-Referred Samples

BY EDGAR P. NACE, M.D., SP5 ANDREW L. MEYERS, USA, AND JOSEPH M. ROTHBERG, PH.D.

The authors report that addicts who volunteered for an Army heroin treatment program differed from those who were detected by urine screening in that they had displayed a greater degree of antisocial behavior in civilian life and had more frequent psychiatric contacts in the service as well as a more extensive history of drug use. The finding that drug use is less frequent during the earliest months of military training than during both the preceding civilian months and the later phases of military duty suggests that recognition and intervention during the early months of military training may be the chief means of primary prevention.

BY 1970 PUBLIC ATTENTION had been drawn to the fact that an epidemic of heroin addiction was unfolding among American military personnel serving in the Republic of Viet Nam (1–3). The history of this epidemic and the factors involved in the spread of heroin in Viet Nam have recently been described (4). Prominent among the factors was a readily available supply of inexpensive highly purified heroin and a social network among peers that supported heroin use (5).

Before July 1971, any attempt to study addicted Viet Nam veterans was hindered by the fact that only those who sought help were available for research purposes. By July 1971, the U.S. Army had initiated a urine-testing program to detect heroin users among soldiers leaving Viet Nam. This program made available for research heroin addicts who had not voluntarily sought help for their addiction and who would possibly not have been identified otherwise. An opportunity was therefore available to investigate possible differences between two groups of addicted Viet Nam veterans: one group who voluntarily sought help from a medical facility in the United States for a problem related to addiction before the onset of the urine-testing program (henceforth called the self-referred group) and a second group who had not voluntarily sought medical help for narcotic addiction but were detected and confirmed as heroin users by the obligatory urine-testing program as they left Viet Nam between August and November 1971 (henceforth called the system-referred group). The members of both groups became addicted to heroin while serving in Viet Nam and had no prior history of addiction.

This paper describes the differences between these two groups of addicts and provides data suggesting that the early phases of military training may be a useful focus for drug abuse intervention efforts.

METHOD

Between December 1970 and November 1971, we screened more than 100 men who were active-duty enlisted U.S. Army personnel by means of interviews and psychological tests given at mental hygiene facilities of four different Army posts in the United States.

The criteria for inclusion in this study were as follows: 1) the subject had to be an active-duty enlisted man who was being seen in a mental hygiene facility for reasons related to drug abuse, 2) he had to be available to participate in the interview and testing procedures during the time the interviewers were at the clinics (of those who met the above criteria, fewer than ten percent refused to participate), and 3) he had to have become addicted while in Viet Nam.

Of the 36 men who met the three criteria, 18 were self-referred and 18 were system-referred. Each soldier was interviewed individually in a semistructured manner for one to one and one-half hours; he spent additional time completing paper-and-pencil tests. It was emphasized that if he felt unable to answer certain questions, he was to indicate that this was so. This underlined our emphasis on accurate information and our preference for no information rather than false information.[1]

The responses to the questions about drug use were categorized into six classes of drugs (marijuana, hallucinogens, amphetamines, barbiturates, narcotics, and "other") and four levels of use: none, moderate (one to ten times per month), heavy (11–50 times per month), and intensive (more than 50 times per month).

The time of initial addiction was operationally defined

At the time this paper was written, the authors were with the Department of Psychiatry, Division of Neuropsychiatry, Walter Reed Army Institute of Research, Washington, D.C., where Dr. Nace was Research Psychiatrist, Specialist 5 Meyers was Social Work-Psychology Specialist, and Dr. Rothberg is Mathematician. Dr. Nace is now Director, Alcoholic Treatment Program, Institute of the Pennsylvania Hospital, 111 West 49th St., Philadelphia, Pa. 19139, and Assistant Professor of Clinical Psychiatry at the University of Pennsylvania.

[1] The validity of interview material obtained from addicted subjects has been demonstrated by Ball (6) and Stimson and Ogborne (7). During the early phases of our study we obtained from the military records validation data on five pieces of interview information for 31 subjects. Agreement between the records and the interview averaged 89.9 percent (range: 65 percent to 100 percent).

as the month in which the subject first reported using heroin three or more times a day. No subject was considered addicted unless he reported using heroin three or more times a day for several months or reported subsequent withdrawal symptoms.

RESULTS

The self-referred and system-referred groups were not significantly different in their employment history, demographic makeup, family background, medical history, or frequency of civilian psychiatric contacts (see table 1). The average age of the subjects at the time of their induction into the Army was 18.5 years for the self-referred group and 19.7 years for the system-referred group. Their average age at the time of their addiction was 19.6 for the self-referred group and 21.1 for the system-referred group. The average age of the self-referred group at the time of their first contact with the Mental Health Consultation Service was 20.4 and that of the system-referred group was 21.8. The average age of the self-referred group at the time of the interview was 20.9; that of the system-referred group was 21.8. The self-referred group had received an average of 10.7 years of education; the system-referred group, 10.8. By the time of the interview, the average length of service was 2.6 years for the self-referred group and 2.1 years for the system-referred group. Fifty percent of both groups were from level IV of the Hollingshead and Redlich socioeconomic scale. The ratio of blacks to whites was 3:15 in both groups and the ratio of single to married men was 15:3 in both groups. Twelve of the self-referred group and 14 of the system-referred group came from cities of more than 50,000 people. The ratio of draftees to enlisted men was 3:15 in both groups. The median rank of the self-referred group was E-3; that of the system-referred group was E-4.

TABLE 1

Medical, Family, Employment, and Behavioral Characteristics of Two Samples of Viet Nam Veterans

Characteristic	Number of Subjects	
	Self-Referred (N=18)	System-Referred (N=18)
Medical history—civilian

*Significant at $p<.05$, using the Fisher exact test.
**Significant at $p<.01$, using the Fisher exact test.
***Defined as employment for at least four years before the interview and including time spent in military service and time spent as a full-time student.

Differences Between Self-Referred and System-Referred Patients

An examination of antisocial behavior, military psychiatric contacts, and patterns of drug use does reveal differences between the two samples (see table 1):

Antisocial behavior. During civilian life the self-referred group had engaged in significantly more acts of delinquency (fighting, truancy, school suspensions, traffic violations) and crimes against property (burglary, auto theft, larceny, shoplifting). They were also arrested, jailed, or put on probation significantly more often than the system-referred group.

During their military service, both groups showed a marked drop in these indices of antisocial behavior, and there were no statistically significant differences between the two groups. Similarly, the number of subjects receiving military disciplinary action (nonjudicial punishment or court martial) did not differ between the two groups.

Psychiatric contacts. Compared with the system-referred group, a significantly greater ($p<.05$) number of the self-referred group contacted a mental hygiene facility while in the Army (see table 1). This calculation excludes the contact during which our interviews were conducted. In spite of extensive drug use, only one of the 36 subjects had contacted an Army mental hygiene facility before becoming addicted to heroin.

It is of interest to examine the length of time between the onset of addiction and contact with a treatment facility. When interviewed for this study, the self-referred group had been addicted for an average of 16 months while the system-referred group had been addicted for an average of nine months. Considering the time span from onset of addiction to initial psychiatric contact (not necessarily the contact during which our interviews were conducted), the self-referred group made initial contact with a treatment facility an average of nine months after becoming addicted and the system-referred group an average of eight months after becoming addicted. Therefore, the self-referred subjects were seen at a treatment facility almost as early in their addiction as the group detected by urinalysis.

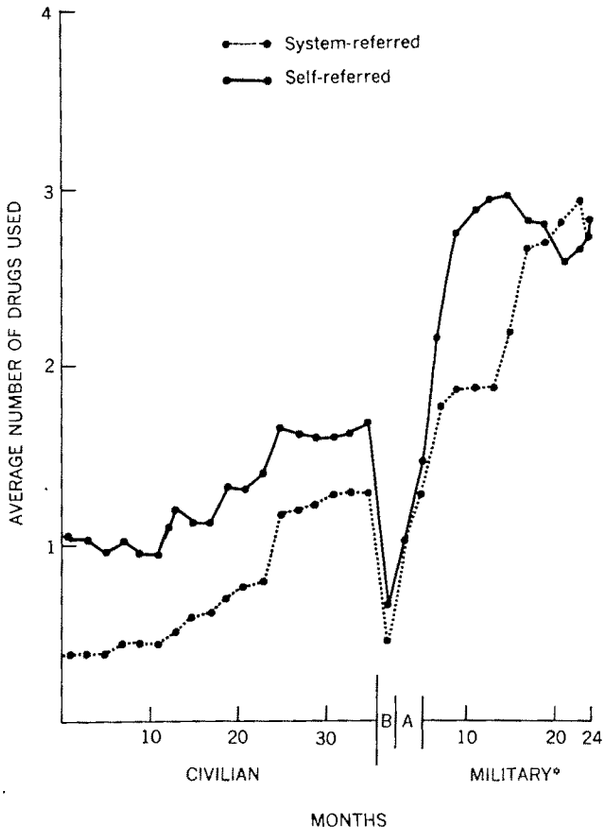
Patterns of drug use. The most consistent difference

between these two groups lies in the more extensive history of drug use reported by the self-referred group. Although both groups are similar on demographic variables and both first became addicted while serving in Viet Nam, there were differences in their use of drugs before they entered the Army. These differences were maintained while they were in the Army, not only during the period before they were sent to Viet Nam, but during the Viet Nam tour as well.

The self-referred group began using illegal drugs (excluding alcohol) at an average age of 15.3 years, compared with 17.4 years for the system-referred group ($t=2.24$, $df=34$, $p<.05$); they first experimented with narcotics at an average age of 18.6 years, compared with 20.4 years for the system-referred group ($t=2.53$, $df=34$, $p<.02$).

A comparison was made of the extent of drug use by the two groups of addicted Viet Nam veterans.[2] Before entering the Army, the self-referred group had a significantly greater number of man-months of use in all categories except narcotics ($p<.01$) and had a significantly greater number of man-months of heavy use (more than ten times a month) in all categories except narcotics and "other" ($p<.01$). A rather marked difference in drug use between the two groups is therefore apparent before their entry into the Army.

There was a precipitous drop in drug use during the two-month period of basic combat training; no significant differences between the groups were found. No heavy use was reported during this phase of training except for a few subjects in both groups who smoked marijuana.



During advanced individual training, the three-month period following basic combat training, drug use began to increase for both groups; however, the self-referred group significantly exceeded the system-referred group only in the use of hallucinogens ($p<.05$).

In the period between advanced individual training and their assignment to Viet Nam, the self-referred group used marijuana, hallucinogens, and narcotics significantly more extensively ($p<.01$), but relatively little heavy drug use occurred. The differences between the two groups during this period are all the more noteworthy considering that the average waiting period for the self-referred group was one-third as long as that for the less drug-involved system-referred group.

Both groups first became addicted to heroin in Viet Nam. However, the self-referred group used marijuana and "other" drugs more often than the system-referred group ($p<.01$) and had a greater amount of heavy use of marijuana ($p<.02$) and of hallucinogens, barbiturates, and "other" drugs ($p<.01$).

Figure 1 compares the average number of drugs used by each of the two groups of addicted Viet Nam veterans during the 36 months before they entered the military and their first 24 months in the service. The figure illustrates the greater number of drugs used during civilian life by the self-referred group, the sudden drop in drug use by both groups upon entering the service, and the subsequent upswing above civilian levels after their advanced individual training. These differences between the two groups of addicted Viet Nam veterans involved both the number of drugs used and the extent of use of each drug.

FIGURE 1
Average Number of Drugs Used Before, During, and After Training Phases

* "B" refers to basic combat training and "A" to advanced individual training.

DISCUSSION

The data demonstrate that soldiers who became addicted in Viet Nam could be distinguished by the manner in which they came to the attention of mental hygiene facilities. This was true in spite of their similar demographic characteristics and the similar environments in which their addiction first occurred.

The variability that exists between and within the samples of addicts who have been studied emphasizes the necessity of avoiding stereotyped images of the addicted (8) and establishing a broad spectrum of treatment goals (9).

[2] The contingency chi square (with Yates' correction where appropriate) was used to express the differences in man-months of use for each class of drug. In all comparisons that were statistically significant, the direction of the difference was that of greater use by the self-referred group. Tabular material containing the chi-square values may be obtained from the authors.

It is likely that the self-referred group would require a more extended and concentrated medical-psychiatric treatment effort than the system-referred group. This supposition is based on the self-referred group's greater degree of maladaptive characterological problems, as evidenced by their history of antisocial behavior and previous psychiatric contacts. Further, the self-referred group's use of heroin had become chronic by the time they were interviewed, since they had been addicted for an average of 16 months by that time.

On the other hand, the fact that the self-referred group had come to the treatment facility voluntarily, relatively early after the onset of addiction, suggests that constructive intervention is at least a possibility with this population. Unfortunately, such an intervention was not accomplished for the subjects under consideration in this study. Nevertheless it is important for mental hygiene personnel to realize that they have the opportunity to intervene relatively early in the heroin-using "careers" of many soldiers.

The data suggest a focus for such intervention efforts. Figure 1 shows that during the earliest phases of military training (basic combat training and advanced individual training) a marked drop in drug use occurs. Given the highly structured and supervised environment of these training periods, it may be assumed that soldiers who use drugs during these phases are those with a relatively greater drug need and those who will be most willing to assume greater risks to obtain drugs. Such subjects are likely to be at high risk for eventual addiction.

Intervention with even the relatively small number of drug-using soldiers who might be known to medical personnel during basic combat training and advanced individual training would not be a trivial event. Even a few persons may spread the use of drugs to others through social relationships, as has been demonstrated by Hughes and colleagues (10). The drug user may serve as the originator of a drug distribution network among his peer group since procurement and distribution become more feasible, as well as more profitable, when greater numbers are involved. An attempt to intervene with these subjects during the early phases of their military training may have favorable epidemiological consequences, since their own drug use as well as their potential for spreading drug use to others would be restrained. The most effective form of intervention has not yet been determined, but the possibilities would include such techniques as community supervision like that in the California parole program (11), assignment to a special medical treatment facility (12), and the currently used individual and group counseling techniques. Or basic combat training and advanced individual training could be considered screening periods for drug abuse in which those who are detected as heroin users would be discharged from the service.

Whatever its nature, early intervention with a person who will almost certainly become a chronic drug user may prevent the development of a drug distribution network. If a treatment model is established as the intervention of choice, success is likely to be increased by providing treatment early in a setting that enhances the commitment of the client to the therapy. This alternative is preferable to that in which the accidentally detected heroin user grudgingly goes through the motions of participating in an obligatory treatment program.

Popular Attitudes and Beliefs About Tranquilizers

BY DEAN I. MANHEIMER, M.A., SUSAN T. DAVIDSON, MITCHELL B. BALTER, PH.D., GLEN D. MELLINGER, PH.D., IRA H. CISIN, PH.D., AND HUGH J. PARRY, PH.D.

In a nationwide survey of the extent and nature of psychotherapeutic drug use, respondents were also questioned about their knowledge of tranquilizers and their attitudes toward the use of these drugs in general and in specific situations. The survey revealed surprising similarities of attitudes across demographic subgroups. Although respondents believed in the efficacy of tranquilizers and were willing to condone their use in some specific circumstances, they also had doubts about their long-term effects and about the morality of using them. Doubts about the morality of using tranquilizers were associated with traditional stoic values.

THE RISING POPULARITY of psychotherapeutic drugs [1] since the introduction of tranquilizers in the mid-1950s has resulted in much public attention and concern about the amounts of these drugs people are using and the vast numbers of people who are using them. Quite apart from the medical issues involved, some social commentators fear that widespread use of these mood-changing drugs is indicative of major undesirable changes in the American character. Some see increased drug use as a cause, others as a consequence, of a general moral decline. Many critics believe that the use of psychotherapeutic drugs indicates weakness and undermines the values of self-reliance, self-control, and will power in coping with problems. There is a related belief that the use of medications that provide symptomatic relief necessarily reduces one's motivation or ability to deal with problems directly.

Much of the discussion about drug-taking practices and the characteristics of users has occurred in the absence of adequate data. Reliable answers are needed for the following questions: How many people are using mood-changing drugs? What are the characteristics of the drug users? How often and for how long are the drugs being used? How prevalent are the emotional and somatic disorders for which use is indicated? How severely distressed are those who obtain drug treatment? What are the popular attitudes and beliefs regarding use of psychotherapeutic drugs? How are these attitudes related to drug-use experience and to more general beliefs and values?

This article will focus on attitudes and beliefs about drug use. Two companion papers report on the prevalence of drug use, characteristics of users, and the prevalence and severity of symptoms for which psychotherapeutic drugs are being used (1, 2). The data reported in all three papers were collected as part of a nationwide survey on the extent and nature of psychotherapeutic drug use in the United States. Taken together, the three papers should provide a basis for a more rational evaluation of the personal and social implications of this drug use than has been possible until now.

[1] By "psychotherapeutic drugs" we mean mood-changing drugs that are used as medicines to alleviate psychic distress or as adjunctive treatment of physical disorders and that are typically acquired through a doctor's prescription.

Topical Papers is a new section of the Journal. *The papers in this section are grouped around a given topic. Publication here does not, however, imply that the Editors consider this material to constitute a comprehensive analysis of the topic.*

is based is the most recent in a series of surveys carried out jointly by the Institute for Research in Social Behavior, Berkeley, Calif., and the Social Research Group of George Washington University, Washington, D.C., with the support and close collaboration of the Psychopharmacology Research Branch of NIMH.

The data for the survey were collected in late 1970 and early 1971. Respondents were selected by rigorous probability sampling methods to ensure a representative cross section of noninstitutionalized American adults. The data were obtained in personal interviews with 2,552 persons from 18 to 74 years of age living in the contiguous United States. These 2,552 persons represented more than 85 percent of the original sample.

The interviews ranged in length from 60 to 90 minutes. In addition to a detailed set of questions about the use of psychotherapeutic drugs, questions were asked about the respondent's general state of health, various psychic and somatic symptoms to which he might be subject, the occurrence of major life crises that might have resulted in emotional distress, and knowledge about and attitudes toward tranquilizers.

The first question asked concerning drugs was "What does the term 'tranquilizer' mean to you—that is, just what would you say a tranquilizer drug or pill is?" After a series of questions about the use of psychotherapeutic drugs, we asked questions designed to assess attitudes and beliefs about such use. One series of questions on attitude dealt only with tranquilizers—their effectiveness, the morality of using them, their impact on mood and behavior, and the short- and long-term physical effects and risks associated with their use. We chose to ask about tranquilizers because they are the most frequently used and most highly publicized psychotherapeutic drugs.

In another series of questions employing a different approach, respondents were asked whether or not they would condone the use of drugs in several concrete problem situations with varying social contexts and degrees of distress. Parallel sets of questions were asked concerning use of drugs to alleviate anxiety and depression. Our intent was to determine general levels of permissiveness with respect to drug use in different social contexts and under varying degrees of impairment.

KNOWLEDGE ABOUT TRANQUILIZERS

Most people do know what effect a tranquilizer has. When asked to describe the meaning of the word "tranquilizer," almost 70 percent of the respondents gave definitions that explicitly mentioned a tranquilizer's desired effect—to calm, relax, or relieve tension or anxiety. Only 11 percent said they did not know what a tranquilizer was,[2] and another three percent gave definitions that were clearly incorrect. The remainder responded either with value judgments or vague descriptions that applied as well to other drugs as to tranquilizers—e.g., "pill for mental patients," "makes you feel better," "it's habit forming," "makes you sleep," "they're bad for you . . . shouldn't take them."

Not surprisingly, knowledge about tranquilizers varied with age and education. For example, 23 percent of the respondents aged 60 to 74 said they did not know what a tranquilizer was, in contrast to four percent of the 18- to 29-year-olds. And although 22 percent of those with less than a high school education said they were unable to define a tranquilizer, the corresponding number among college-educated respondents was only three percent.

All data reported in the remainder of this paper exclude respondents who said they were unable to define a tranquilizer.

ATTITUDES AND BELIEFS ABOUT TRANQUILIZERS

Respondents were asked whether they agreed or disagreed with a wide range of statements of attitudes and beliefs about minor tranquilizers. These statements were presented to respondents with the following instructions:

> Now I'm going to give you a list of statements people have made about tranquilizers—that is, pills such as Miltown, Equanil, and Librium that can be used to calm you down or keep you from getting nervous or upset. As you read each statement, please . . . tell whether you agree strongly, agree, disagree, or disagree strongly.

The percentages of respondents agreeing and disagreeing with the various statements are shown in table 1. Items that reflect similar issues are grouped under the same topic heading. Note that these data show only the extent to which people subscribe to the statements and do not necessarily reflect their degree of concern about the issues.

Most respondents believed that tranquilizers are effective calming agents. However, substantial majorities agreed that they don't really cure anything and may even prevent people from working out their problems. The almost 90 percent of respondents who agreed that it is better to use will power to solve problems than it is to use tranquilizers and the sizable number who agreed that taking tranquilizers is a sign of weakness exemplify a stance that Klerman has aptly labeled "pharmacological Calvinism" (4) and suggest that there is considerable conservatism concerning the morality of using psychotherapeutic drugs.

Two items in table 1 deal with the question of control over behavior and mood. About two-thirds of our respondents agreed that tranquilizers can interfere with such control. Agreement with the first of these statements partly expresses the belief that the side effects of tranquilizers can impair mental alertness and physical performance. However, we think that both statements further reflect the belief that tranquilizers generally diminish one's drive, effectiveness, and sense of responsi-

[2] Knowledge about tranquilizers has increased considerably in the last ten years. In 1960, the Psychological Corporation found that 32 percent of the public surveyed could not define a tranquilizer when asked the identical question (3).

TABLE 1

*Percentages Agreeing and Disagreeing with Statements Reflecting General Attitudes and Beliefs About Tranquilizers (N = 2,241)**

Statement	Agree	Disagree	No Answer/ Don't Know
Efficacy			
Tranquilizers work very well to make a person more calm and relaxed.	74	20	6
Self-awareness and problem solving			
Tranquilizers don't really cure anything; they just cover up the real trouble.	69	25	5
Using tranquilizers just prevents people from working out their problems for themselves.	57	37	6
Self-reliance and strength of character			
It is better to use will power to solve problems than it is to use tranquilizers.	87	10	3
Taking tranquilizers is a sign of weakness.	40	55	5
Control and responsibility			
Tranquilizers cause people to lose some control over what they do.	61	31	7
Tranquilizers can change your mood so that you just don't care about anything.	66	28	6
Short-term side effects			
One big advantage of tranquilizers is that they *don't* make a person sleepy or groggy.	12	79	9
Tranquilizers often have bad side effects—such as making a person very sleepy or sick to the stomach.	73	18	9
Long-term adverse effects			
Long-term use of tranquilizers may cause real physical harm to your body.	80	14	6
One good thing about tranquilizers is that people do *not* get addicted to them.	18	74	9
Consumer concerns			
Tranquilizers often get on the market before they are thoroughly tested to be sure they are safe.	57	30	12
Tranquilizers are too new for doctors to know what harm they might do to a person in years to come.	39	52	9
Many doctors prescribe tranquilizers more than they should.	59	30	11

*"Agree" combines the answer categories of "agree" and "agree strongly" and "Disagree" combines "disagree" and "disagree strongly." In most cases the percentages for "agree strongly" and "disagree strongly" were quite small; the exceptions were "It is better to use will power than it is to use tranquilizers" (35 percent agreed strongly) and "Long-term use of tranquilizers may cause real physical harm to your body" (25 percent agreed strongly).

bility. Support for this latter interpretation can be found in the relatively high correlations between responses to these items and the more obviously moralistic ones, e.g., "Taking tranquilizers is a sign of weakness." One respondent's remark typifies this viewpoint: "I want to be in full control of myself, right or wrong; so I don't want some chemical to do something to my system over which I don't have control." Responses to the four items concerning the physical consequences associated with tranquilizer use show that most of our respondents thought that tranquilizers have undesirable side effects and may be physically harmful if used over a long period of time. Many respondents also felt that not enough care was exercised in screening and prescribing these drugs.

In general, it appears that Americans believe tranquilizers are effective but have serious doubts about the morality of using them and about their physical safety. Although these beliefs are by no means unanimous, the degree to which they are held is remarkably similar across the various subgroups for sex, age, education, income, and area of residence. The few clear-cut differences that we did find among demographic groups are shown in table 2. These are differences by educational level on two of the moral issues associated with tranquilizer use. Respondents with the least education were the most likely to agree that using tranquilizers indicates weakness of character and that their use prevents a person from solving his problems himself.

CONDONING DRUG USE

Another way of assessing views about the use of psychotherapeutic drugs is to examine the respondents' willingness to condone their use in a variety of practical circumstances. We described situations involving family or work in which a person might need or want to use such a drug and asked our respondents whether or not they approved of taking a drug in each situation. We further measured attitudes by comparing condoning of drug use for two types of distress—anxiety and depression—at various levels of behavioral impairment within the family and work situations.

Questions about using drugs for anxiety preceded those about using drugs for depression and were widely separated from them in the interview schedule because we wished to minimize bias in responses.[3] The preface to each question and the questions themselves are shown be-

[3] In one of the community studies conducted prior to the national survey, we tested the effect of order by asking half the sample the questions about drug use for anxiety first and the other half the questions about use for depression first. Order had a very small effect on responses. We feel confident that by widely separating these sets of questions in the national survey we have virtually eliminated this effect.

TABLE 2
Percentage Agreeing with Statements About the Morality of Tranquilizer Use According to Educational Level

Statement	Less than High School Graduate (N = 791)	High School Graduate (N = 738)	Some College (N = 405)	College Graduate (N = 305)
Using tranquilizers just prevents people from working out their problems for themselves.	62	58	54	44
Taking tranquilizers is a sign of weakness.	50	40	34	29

low (the alternate drug description is enclosed in parentheses). Notice that the emphasis was on the effects the drugs produce rather than on names of drug classes.

> Let's assume that someone has a supply of pills on hand that a doctor prescribed and said to take as needed. These pills calm you down or make you feel more relaxed (*or* These pills make you feel more energetic or alert, or lift your spirits). Just suppose that the person is trying to decide whether to take one in each of the following situations. Do you agree or disagree that it's all right to take a pill or medicine like this when someone:
>
> 1. is generally doing a good job at work but wants to be relaxed (*or* to have more energy) in order to be even more efficient and productive?
> 2. is upset and nervous (*or* is down in the dumps or has little energy) and not working as well as he should?
> 3. is so upset or nervous (*or* is so depressed or has so little energy) that he is not even able to go to work?
> 4. wants to relax (*or* wants more energy) in order to enjoy his family more than usual?
> 5. is nervous and upset (*or* is depressed) and can't get along with his family as well as usual?
> 6. is so upset and nervous (*or* is so depressed or has so little energy) that he is making life miserable for his family?

These situations differentiated among three levels of functioning: items 1 and 4 described drug use to enhance normal functioning; items 2 and 5 described use to offset a moderate deficit in functioning; and items 3 and 6 described use to offset a major deficit in functioning. Table 3 shows the percentages of respondents who condoned using the drug in each situation.

TABLE 3
Percentage Condoning Drug Use for Anxiety and Depression Under Various Conditions of Social Functioning (N = 2,241)

Condition	Drug for Anxiety	Drug for Depression
In work context		
1. To enhance normal functioning	13	8
2. To offset moderate deficit	55	38
3. To offset major deficit	64	50
In family context		
4. To enhance normal functioning	19	17
5. To offset moderate deficit	48	37
6. To offset major deficit	62	48

It is apparent from table 3 that the number of respondents approving of drug use increased with the severity of the impairment described. This finding is consistent for both types of distress and for both work and family settings. For example, when asked about use of a drug to calm a person down or make him feel more relaxed in the context of work, only 13 percent condoned use "to be even more efficient and productive," whereas the majority condoned use "when someone is upset and nervous and is not working as well as he should." This finding reflects the judgment that it is all right to take a drug to correct a significant deficit in ability to function in a vital life situation, but that it is definitely not all right to use a drug simply because a person wants to function better than he normally does.

Not apparent from table 3 is the fact that some respondents who approved of taking a drug when there is a mild difficulty in functioning did not agree to its use at the maximum level of distress described. Among those who sanctioned drug use for anxiety when there is moderate impairment in functioning at work, one-fifth disagreed to its use "when someone is so upset or nervous that he is not even able to go to work." These people frequently commented that anyone who is having such severe problems should be seeing a doctor or psychiatrist rather than simply taking a pill.

Although the extent to which use was sanctioned is roughly the same for both life contexts (family and work), people were more willing to condone the use of an anti-anxiety agent than they were to condone the use of an antidepressant. This is particularly evident in the situations involving difficulty in functioning. Why should this difference in attitude exist? We think it may reflect different social attitudes toward anxiety and depression.[4] We also suspect that, although we did not specifically name any drugs, the description of a pill to "make you feel more energetic or alert" conjured up a vision of

[4] We considered the possibility that the relative prevalence of anxiety and depression among respondents in our sample could partly account for this finding. This was not the case. Respondents who reported experiencing anxiety were no more likely to condone drug use for anxiety than for depression. Similarly, those who had experienced a variety of depressive symptoms were as likely to condone use for anxiety as they were for depression. Both groups were more likely to condone use of drugs for both types of distress than were respondents who had not experienced either type of distress.

TABLE 4
Percentage Condoning Drug Use for Anxiety in Work Context According to General Attitudes Toward Tranquilizers

Statement	Opinion*	Number	Condition—Work Context: To Offset Moderate Deficit	Condition—Work Context: To Offset Major Deficit
Tranquilizers work very well to make a person more calm and relaxed.	Agree	1,651	61	69
	Disagree	454	33	46
Using tranquilizers just prevents people from working out their problems for themselves.	Agree	1,264	45	57
	Disagree	840	70	75
Taking tranquilizers is a sign of weakness.	Agree	922	41	53
	Disagree	1,206	65	72
Tranquilizers cause people to lose some control over what they do.	Agree	1,370	47	58
	Disagree	698	71	76
Tranquilizers often have bad side effects—such as making a person very sleepy or sick to the stomach.	Agree	1,632	52	62
	Disagree	405	68	72
Long-term use of tranquilizers may cause real physical harm to your body.	Agree	1,770	52	62
	Disagree	331	70	73

*"Don't know" or "no answer" responses are omitted.

the notorious "pep pill."

The percentages did not vary much from those presented in table 3 when comparisons were made on the basis of such demographic variables as age or sex. The one exception was a comparison based on the region of the United States in which respondents lived. More westerners sanctioned the use of psychotherapeutic drugs than did residents of other areas of the United States. Although none of the differences was great, the gap between the West and the rest of the country was consistent for all six situations described. This parallels the higher rate of psychotherapeutic drug use reported for the West (1).

The extent to which condoning drug use was related to some of the beliefs about tranquilizers discussed earlier is shown in table 4. For ease of presentation, we have selected six items from table 1 to represent the issues of efficacy, morality, control over behavior and mood, and the short- and long-term physical effects associated with tranquilizer use. In table 4 (and in all subsequent tables that contain data concerning general attitudes and beliefs about tranquilizers) only these six items will be used.[5] It should be noted that although we show data only for work-related situations, the relationship was similar for family-related situations.

Respondents whose general attitudes toward tranquilizers were negative were less likely to condone the use of such drugs in specific situations than were those whose general attitudes were positive. However, even among respondents who were negatively disposed in general, the majority were willing to condone the use of tranquilizers when asked to make a judgment about a concrete situation. Even among those who equated tranquilizer use with personal weakness, over half condoned such use by someone who is so upset that he is not even able to go to work. No doubt this is partly explained by the fact that we asked our respondents to assume that the person described in each situation already had a supply of tranquilizers on hand that a doctor had prescribed to be used as needed. But we also think this seeming inconsistency between general attitudes and willingness to condone use in concrete situations exemplifies the actual conflicts many people experience with respect to the use of psychotherapeutic drugs.[6] On the one hand they believe that unpleasant side effects and physical dangers are associated with their use, that taking drugs of this type implies weakness, and that using them may prevent the solution of personal problems. On the other hand they believe that such drugs are effective in relieving emotional distress and apparently feel that their use is warranted in concrete situations in which important life activities or relationships are threatened.

It seems clear from table 4 that beliefs about the short- and long-term physical consequences of tranquilizer use are not very strongly related to willingness to condone use. An analysis of the joint effects of the six items shows that the issues of morality, behavioral consequences, and efficacy are more influential in the decision to condone use than are beliefs about negative physical consequences.[7]

[5] An examination of data not presented here revealed that the patterns shown for these six items are typical of the content area each represents. For example, the pattern for the item concerned with addiction is almost identical to that concerned with long-term use and harm to the body. We omitted items in the area of consumer concern because they were more concerned with social institutions than with intrinsic characteristics of tranquilizers or their users.

[6] Doubts about tranquilizers may also apply to drugs that are not psychotherapeutic, of course. Nevertheless, tranquilizers and other psychotherapeutic drugs probably cause greater conflict than do drugs that are considered "medicines" for primarily somatic complaints.

[7] At least this is so with respect to the practical situations we described. It is conceivable that the long-term safety of tranquilizer use would appear as an issue of first importance if we had asked our respondents to condone long-term use.

TABLE 5
Percentage Agreeing with Statements About Tranquilizers According to Score on the Stoicism-Traditionalism Index

Statement	Stoicism-Traditionalism Score				
	0–1 (N=156)	2–3 (N=797)	4 (N=595)	5 (N=480)	6 (N=213)
Tranquilizers work very well to make a person more calm and relaxed.	74	78	74	73	62
Using tranquilizers just prevents people from working out their problems for themselves.	43	51	60	61	70
Taking tranquilizers is a sign of weakness.	27	33	42	50	60
Tranquilizers cause people to lose some control over what they do.	50	56	63	69	71
Tranquilizers often have bad side effects—such as making a person very sleepy or sick to the stomach.	72	72	73	75	78
Long-term use of tranquilizers may cause real physical harm to your body.	72	79	82	82	81

ATTITUDES TOWARD TRANQUILIZERS AND VALUE ORIENTATIONS

In our investigation we also considered the question of whether attitudes toward tranquilizers stand in isolation or are related to larger value orientations or a broader social ethic—in particular, to values that reflect the "work, achieve, succeed, do not complain" orientation commonly associated with the Protestant ethic. To examine this dimension we constructed an index that we called "stoicism-traditionalism." The index items were contained in a questionnaire completed by respondents after the interview. There were four true-false items:

Even if a person has troubles there is no reason why he cannot keep up a cheerful front.
We should bear our troubles bravely and not complain.
There is something wrong with a person who is not willing to work hard.
I always follow the rule: "business before pleasure."

Each of these items was given a score of 1 if the respondent answered "true." The following six items were presented as statements people might like to make about themselves in looking back over their lives:

1. I have enjoyed life and had fun.
2. I have been loved.
3. I have always done my work to the best of my ability.
4. I have enjoyed the beautiful things in life.
5. I have made a lot of money.
6. I have lived a moral, respectable life.

The respondents were asked to indicate the importance of each by ranking it in relation to the other five. If items 3 and 6 were ranked within the first three, each was given a score of 1. The item scores were summed to produce an index score from 0 to 6.

The relationship between scores on the stoicism-traditionalism index and attitudes toward tranquilizers is shown in table 5. Agreement with the statement embodying the essence of pharmacological Calvinism—"Taking tranquilizers is a sign of weakness"—is strongly related to a high score on the stoicism-traditionalism index, whereas beliefs about physical risks are virtually unrelated. Note also the large percentage differences between the low and high scorers with regard to the statements concerning loss of control and interference with problem solving. We believe that these are further illustrations of the strong influence of moral values in matters concerning psychotherapeutic drug use. The relationship between these drug attitudes and general value orientations is fairly constant for all demographic groups. For example, even though older people tend to score higher on stoicism-traditionalism than do younger people, the relationship between traditional stoic values and the belief that tranquilizer use is a sign of weakness remains constant for the two groups.

ATTITUDES TOWARD TRANQUILIZERS AND MENTAL ILLNESS

We examined the relationship between attitudes toward the use of tranquilizers and attitudes toward mental illness on the assumption that views about the legitimacy of use might, in part, reflect attitudes about the legitimacy of psychic illness. To do this we used data from a large community study carried out in Contra Costa County—an area suburban to San Francisco—roughly 18 months before the national survey. In the Contra Costa study we included the following true-false item: "One of the main causes of mental illness is lack of moral strength or will." About 40 percent agreed with this statement, and those who agreed with it were more than twice as likely as others to agree that taking tranquilizers is a sign of weakness (the same general relationship held true for other items that were concerned with undesirable moral and behavioral consequences of tranquilizer use). Both of these beliefs were associated with lower educational attainment. Because the Contra Costa sample had on the whole a much higher level of education than

TABLE 6
Percentage Agreeing with Statements About Tranquilizers According to Personal Use of Prescription Psychotherapeutic Drugs

Statement	Tranquilizer Users* (N=652)	Nontranquilizer Users (N=386)	Nonusers of Psychotherapeutic Drugs (N=1,203)
Tranquilizers work very well to make a person more calm and relaxed.	85	79	67
Using tranquilizers just prevents people from working out their problems for themselves.	42	58	63
Taking tranquilizers is a sign of weakness.	30	38	46
Tranquilizers cause people to lose some control over what they do.	48	61	68
Tranquilizers often have bad side effects—such as making a person very sleepy or sick to the stomach.	68	72	76
Long-term use of tranquilizers may cause real physical harm to your body.	74	80	83

*Because a few respondents were unable to identify a drug they had used by name but could only describe the drug by its function, e.g., "a drug to calm my nerves," "tranquilizer" is here defined as a combined class of tranquilizers and sedatives. Of this group of users, 78 percent had used a named tranquilizer; 12 percent had used an unidentified sedative or tranquilizer in order to become calm. Only nine percent had used a sedative and not a tranquilizer, but of course some of these took the sedatives specifically for their calming action.

our national sample, it is reasonable to assume that in the national sample an even higher proportion consider mental illness a consequence of moral weakness and that the relationship between this attitude and beliefs about the morality of using tranquilizers is at least as strong. The proportion of respondents who agreed that taking tranquilizers is a sign of weakness was 30 percent in the Contra Costa sample and 40 percent in the national sample.

ATTITUDES TOWARD TRANQUILIZERS AND PERSONAL DRUG USE

Table 6 shows how beliefs about tranquilizers are related to personal experience with prescription psychotherapeutic drugs. Respondents are divided into three groups on the basis of lifetime experience with psychotherapeutic drugs: those who have used prescription tranquilizers (tranquilizer users), those who have used another prescription psychotherapeutic drug but not a tranquilizer (nontranquilizer users), and those who have never used any prescription psychotherapeutic drug.

Differences between prescription tranquilizer users and those who have never used a prescription psychotherapeutic drug are significant, except with respect to opinions on short-term side effects and long-term physical harm. Those who have used only prescription nontranquilizers view tranquilizers with less favor than do tranquilizer users but with more favor than nonusers.[8] The consistently intermediate position that users of nontranquilizing drugs have with respect to all items in table 6 suggests that attitudes and beliefs about tranquilizers do reflect more general beliefs about psychotherapeutic drugs.

It is apparent from table 6 that, even though differences between users and nonusers are pronounced, a large percentage of users also hold unfavorable opinions about tranquilizer use. These findings argue strongly that people are not being misled into believing that tranquilizers are a magic solution to their problems.

Although it is tempting to make inferences regarding the influence of attitudes on use and of use on attitude, we cannot properly do so. The attitude data and the use data were collected at the same time; thus there is no way we can determine whether particular attitudes and beliefs preceded or followed use of a psychotherapeutic drug. It is clear that beliefs can be influenced by experience. Studies of cognitive dissonance, in particular, suggest that, when beliefs and behavior are inconsistent, beliefs are likely to be reinterpreted to support the behavior (5). What hints we can coax from our data tend to support this finding, as well as the view that those with values and beliefs opposing the use of drugs are less likely than others to use them.

CONCLUSIONS

There is considerable evidence that Americans believe in the efficacy of psychotherapeutic drugs but have doubts about the virtue of using them. These doubts encompass immediate and long-term physical effects as well as potential moral and behavioral consequences, such as losing control over one's actions or a reduced sense of responsibility. In addition, many people feel that the use of drugs that simply alter a mood or emotional state may mask symptoms or reduce motivation to change, thus interfering with the solution of underlying problems. Others feel that such drug use is clearly a moral or characterological issue; this was reflected in the large proportion of people who agreed with the blunt

[8] Additional comparisons (not shown) between users of prescription psychotherapeutic drugs and users of over-the-counter varieties exhibited the same pattern. Those who had used over-the-counter drugs were more likely than those who had never used any psychotherapeutic drugs to have favorable attitudes toward tranquilizers and less likely than prescription nontranquilizer users to have favorable attitudes toward tranquilizers.

statement that taking tranquilizers is a sign of weakness.

Beliefs about psychotherapeutic drugs do seem to reflect a general moral stance—particularly concerning the values of strength and self-denial associated with the Protestant ethic. Consistent with such values is the finding that people are very unlikely to condone the use of a psychotherapeutic drug except in situations involving a real threat to important relationships or the ability to carry on important activities, such as work.

What is more remarkable is how consistent these beliefs and attitudes were among demographic subgroups of the population. Except for a tendency toward more liberal attitudes in the West and a greater likelihood for the least educated respondents to equate character weakness with the use of psychotherapeutic drugs, we found a striking similarity of attitudes among persons of disparate age, income, education, occupation, and sex. Clear-cut differences in attitude do exist between those who have used psychotherapeutic drugs and those who have not. Those who have used such drugs are more favorably disposed toward them on all the major issues we explored than are those who have never used such drugs. But even those who have used psychotherapeutic drugs appear to have considerable reservations regarding their use and do not appear to believe that drugs are an instant solution to all of life's difficulties and problems.

Although our findings suggest that people are more conservative in their approach to psychotherapeutic drugs than much of the current literature suggests, we want to stress the fact that no conclusions about the long-term implications of these findings can be reached. The relationship between attitudes toward drugs and use of drugs is complex. The decision to use or not use a psychotherapeutic drug is the result of a process involving many variables, including intensity of need and availability of alternative ways of resolving problems and relieving symptoms. Conversely, one's attitudes toward drugs are influenced by many personal experiences, including past use of drugs.

The Road to Shangri-La Is Paved with Vitamins

BY REUBEN BITENSKY, PH.D.

A number of people have adopted a belief that vitamins can prevent disease and restore youth. The author examines the implications of this belief as it was uncovered in group therapy sessions. He discusses the liberalism and activism of these middle-aged group members in their younger years, the anti-establishment values of the vitamin cult, and the denial of aging by seeking eternal youth. The author concludes that their common belief in the powers of vitamins has not been beneficial to the growth and well-being of the group.

MUCH OF THE CONTROVERSY that has raged over the medical worth of vitamins has neglected to consider why a scientific issue should stir up such vehemence. In the heat of battle the contestants have not paused to ask why they are involved in the fray. The passions that have been aroused seem more typical of religious and political conflicts than of the investigations of medical science. Not since the controversy over the fluoridation of water, which has happily abated, has there been such polarization. In fact, "vitaminization" seems more apt to capture the minds and hearts of Americans than Vietnamization. Although I am not equipped to evaluate the therapeutic benefits of vitamins, nor do I wish to, it nevertheless seems to me that the whole subject could be approached more objectively if the psychological and ideological aspects of the vitamin crusade could be examined.

This was brought home to me when, in working with a

Dr. Bitensky is Associate Dean and Associate Professor, School of Social Work, Syracuse University, 926 South Crouse Ave., Syracuse, N.Y. 13210.

number of patients in group therapy sessions, I suddenly found the vitamin cult to be an intruder in our midst. The rapid conversion of the group to this cult first struck me as a benign, if somewhat ironic, eccentricity. It was ironic because all the members of the group were attributing to vitamins some magical potency to ward off disease while they were being beset by various ailments. Indeed, as the group members became freer to disclose their belief, they revealed their conviction that vitamins C and E would not only prevent disease but would restore youth. It seemed to me that in a sense such rallying under the banner of vitamins could be the cause célèbre of the older generation. If past generations could seek organ transplants from monkeys and if the young have their idiosyncracies, then why shouldn't today's older people see vitamins as the elixir of youth and the hope of the future?

However, I was soon to find out that treating the subject with tolerance and dispassion did not evoke a sympathetic chord. The group members interpreted my impartiality as a form of intellectual dilettantism. Moreover, they saw me as an agnostic who was undermining their faith in their tribal god. Thus, as time went on, I began to perceive that this was not merely a scientific dispute, but that it had distinct theological overtones. I began to be aware that a religion was at stake, with its high priests, its doctrines, and its rituals. To question the dogma was to contaminate the deep well of psychological gratification the cult offered its proselytes.

THE NATURE OF THE GROUP

To understand these psychological rewards, the nature of the group has to be considered. They were men and women of later middle age who, although they had achieved some successes in life, were frustrated in attaining the goals they had set for themselves in the sexual, social, and economic spheres, or in a combination of these. At the time they were still highly motivated for the future. What was common to them as a group was a high degree of emotional deprivation because of their failures and an intense investment in filling these lacunae. While these objectives seemed highly unrealistic given the passage of years, nevertheless they clung as a group to the illusion that in the near future—just around the corner—was the ideal love partner, the glittering pot of gold, or the stunning social coup. Unattainable as these goals were, it was maintaining the illusion that was paramount, and even the illusion was in danger of being dimmed by the approach of old age.

The character of this contradiction was brought home to the group members by their awareness that, while the attainment of their desires required ever greater expenditures of energy and will power, the onrush of time was depleting these precious resources. Psychologically, it became imperative to roll back or at least retard the aging process. For without their youth—or what was left of it—the ramparts of their dream worlds would be scaled by reality, and old age would have to be confronted. However, where there is a desire to be psychologically hoodwinked the answer is not long in coming. It was found in vitamins, particularly vitamin E. Here was the panacea for disease, the talisman against the aging process, and the elixir to rejuvenate body and soul.

Although various reasons have been given for the resurgence of the vitamin cult, these explanations tend to be universal in scope and there has been little exploration of why particular groups resort to this psychological pattern. Given the nature of the group I worked with, why did they gravitate to vitamin E? Why not deep-breathing exercises, faith healing, or the transmigration of souls? To understand why a particular group seeks a specific resolution for a problem one must understand not only the problem but also the nature of the group. In this respect, awareness of the psychological needs of the group is a sine qua non; these needs have been identified and described in the psychological and sociological literature on the subject. What has received scant attention is the extent to which ideological imperatives and the value systems of the members of the group may influence the choice of a solution in attaining new psychological levels of adjustment.

This phenomenon was highly visible in the group that I worked with as therapist. All the members of the group were of a progressive inclination and in their youth had ascribed to liberal activism. However, the debilitating effects of the passing years were making it more and more difficult—physically and psychologically—to practice activism. It was becoming less and less inviting to attend meetings, participate in committees, and enter into the political fray. At the same time they were loath to give up their image of themselves as crusaders for progress, for this would lower their own self-esteem as well as imperil the adulation of children, relatives, and friends.

THE VITAMIN CULT AND THE ESTABLISHMENT

Vitamins offered a way out of this cul-de-sac. Adherence to the vitamin cult was a means of preserving their image of themselves as anti-establishment, particularly in regard to the medical sector of the establishment. Had not Linus Pauling postulated that vitamin C was being attacked as a cure for colds because the pharmaceutical companies had a vested interest in spurious cold remedies? Was not vitamin E being downgraded by the medical profession because of its investment in the perpetuation of disease? This charge against the medical establishment in the United States was given all the more credence because of the crisis in the delivery of health services and the resistance of the AMA to liberal solutions. Thus the vitamin evangelists could point to the medical profession's reservations about vitamins as one more example in a long history of opposition to progress in medical service for the populace. (It may be noted, however, that they seemingly took no cognizance of the fact that, with the growing popularity of vitamins, the same pharmaceutical companies were earning substantial profits from the boom in vitamins.)

In another respect the vitamin cult represented an at-

tack upon the establishment through its link-up with the organic food zealots. This occurred because the therapeutic rationale for adding vitamins to the diet arose from the plausible charge that the food industry was processing the vitamins out of many foods. Therefore, the only effective method of getting sufficient vitamins was by the use of organic foods. The resulting alliance between the vitamin and organic food devotees (often they were the same people) brought the vitamin cult into confrontation not only with the medical empire but also with the food industry. Thus a Goliath had been created that would be a worthy adversary of any liberal David.

In such a conflict the image of the political crusader could be maintained and even strengthened with substantial rewards for one's self-concept. But it was crucial to this accomplishment that it involved only a minimal expenditure of energy. By ingesting vitamins one could fight the establishment with the kind of activism that required no more effort than swallowing. Moreover, the greater the dosage, the greater the witness to fervent liberalism and anti-establishment sentiments. The liberals in the group had discovered a holy rite comparable to the sacrament of the Eucharist. Through the substitution of vitamins they had created a political communion through which the dilemma of being a liberal activist without being active was resolved.

However, there was another way in which the vitamin cult answered the psychological needs of the group and this too arose from the anxieties, insecurities, and fears brought on by old age. As the years went by and as illness and thoughts of death loomed larger, the liberal ideology offered less and less consolation to the members of the group. Because of their beliefs it was difficult for them to seek the religious comfort of facing death in the promise of immortality. During their earlier years these liberals were either agnostics or atheists. This presented no problems during their youth and early middle age since illness and death were merely theoretical concepts and not concrete realities that required some psychological readjustment. But to resort to religious belief in later years would be a desertion of the liberal credo and a shattering of the crusading image that was at the core of their personalities. In this crisis it was once again the vitamin cult that unified the seemingly irreconcilable opposites of liberalism and religious orthodoxy.

The problem the group faced was that of staving off death without resorting to religious solutions. Since life in the hereafter could only be assured theologically, a dogma was necessary to provide immortality here on earth. Once again the vitamin cult came to the rescue by promising eternal youth, or at least postponement of the aging process. But why are vitamins more acceptable than other avenues to immortality? Here it becomes evident that the scientific emphasis inherent in the vitamin approach makes it compatible with the agnostic or atheistic value system of the group members. At the same time it also overcame the dilemma inherent in agnosticism and atheism, since it provided a rationale for dealing with death through the so-called youth-preserving properties of vitamins.

Here it is clear that the group members had to choose between two alternatives: they could retain their agnostic and/or atheistic beliefs or they could abandon their beliefs under the subterfuge that they were accepting a more scientific orientation in the vitamin cult. It is sufficient for our purposes to note that maintaining their agnosticism would have meant facing the limitations of old age and adapting to the realities of a new phase in their lives. On the other hand, the vitamin cult could preserve the illusion of youth and enable them to avoid—at least for some time—the necessity of regarding themselves as elderly. Interestingly enough, if character building is to be regarded as the outcome of confronting and dealing with the realities of living, it would have been adhering to their old beliefs rather than seeking the will-o'-the-wisp of eternal youth and the intimations of immortality promised by vitamins that would have contributed to their continued growth as individuals.

THE EFFECT ON THE GROUP

Given this new adjustment, how durable was it? Will this new homeostatic balance promote the cohesion of the group and will it foster the stability of the individual members? Already some stresses and strains are beginning to appear that augur ill for the psychological well-being of the group. There are signs that they are perplexed and uncomfortable with their status as a select group (one that has the quality of eccentricity rather than elitism) that is different from the remainder of society. It is a situation that conflicts with their cherished image of themselves as liberals since, although liberalism implies an advanced role in society, it is an integrated, not a deviant, position.

This insecurity in the group was mirrored in their doubts about the values of their colleagues. While each subscribed to the vitamin cult, they inwardly mistrusted their peers for adopting this stance and criticized them for abandoning the traditional tenets of liberalism. Differences between members of the group were thus exacerbated and they found it increasingly difficult to tolerate each other's company even though they held a common dogma. Only in dialogues about the curative powers of vitamins were they in harmony. However, when faced with the skepticism of friends and acquaintances outside the group, they tended to unite in categorizing the doubting Thomases as irredeemable, unenlightened pagans.

But why is the new psychological adjustment so tenuous? The ability to deal maturely with old age arises out of accepting its inevitability in order to philosophically and morally transcend its limitations. To live by the denial of old age, buoyed by fantasies of great expectations in the future, means to fail to live today. By giving up their value system and failing to face life's limitations the group first of all relinquished their tested liberal values and assumed the mantle of knowledge in an area in which they possessed no more expertise than the man in the street. They gave up being themselves and

took on roles that were unbelievable to their friends. Far from being secure, they became threatened and defensive. Their behavior was guarded, with an increasing lack of variety, nuance, and spontaneity in their thoughts and actions. Previously, when the group sessions first began, their interaction demonstrated their interest in art, politics, and ideas. Now there was a perseverative discussion of their ailments, of vitamins, and of organic foods. Their intellectual horizons extended only far enough to include ecology as a topic of conversation since this was related to the future of organic farming.

In retrospect it is evident that, if the group had refrained from attributing magical therapeutic properties to vitamins and had accepted the inevitability of old age, they could have retained their self-respect and the esteem of their peers. They denied reality as fraught with antithesis and suffering. They chose instead the easy way—the dream of Shangri-La—and, in the frenetic pursuit of their youth, they are in danger of losing what remains of their old age.

Physicians and the New Sexual Freedom

BY IRADJ SIASSI, M.D., AND MIVART THOMAS, M.D.

Articles in the popular press and books by mental health practitioners have raised the question of whether psychiatrists should have sexual relations with their patients. The authors compare the relationship between a physician and a patient with that between a parent and a child and conclude that sexual involvement with a patient impairs the empathy and objectivity that are necessary for therapeutic effect.

THE RISING TIDE of new sexual freedom that has been spreading through American society was bound to reach and challenge the hallowed relationship between physician and patient sooner or later. Typical of this trend was the lead article in a well-known women's magazine "Should You Sleep with Your Therapist? The Raging Controversy in American Psychiatry" (1).

Popular magazine articles, with their bent for sensationalism, can be ignored without much ceremony. The idea, however, seems to go beyond sensational journalism. For example, Dr. Martin Shepard, a psychiatrist with respectable credentials, raises a similar question in an entire book devoted to the subject (2).

Open and honest discussion about all aspects of human sexuality is one of the remarkable achievements of our generation. Another is the acceptance of sexual practices that vary from long-held conventional norms. A nonjudgmental attitude on the part of the physician toward the sexual practices of his patients has become one of the moral dicta of medical education. It was inevitable that the taboo against sexual relations between physician and patient should be challenged, questioned, or at the very least subjected to examination.

In most societies the physician-patient relationship has many of the qualities of the relationship between parent and child, e.g., maximum social intimacy coupled with maximum sexual distance. The fact that the physician is governed by the same sexual taboos that prevail between parent and child makes it possible for him to exercise prerogatives that would be inconceivable in a different situation. Such public trust is absolutely essential for the physician to be allowed to carry out his work; it has therefore been jealously guarded and enforced by both the public and the medical profession.

Just as it is the parent's responsibility not to exploit the dependent and helpless child, so too is it the physician's responsibility in a physician-patient relationship to avoid sexual indiscretion. The fact that the patient is willing, or may even be the aggressive initiator, is no more valid a justification than the claim of parents who engage in incest that the child was willing or was the initiator. For these reasons the medical profession's disciplinary committees have traditionally been very strict in interpreting the medical code of ethics in sexual matters. Retribution against the transgressors has tended to be swift, severe, and uncompromising; it frequently includes the loss of the guilty physician's license to practice. This unequivocal reaction clearly emphasizes the attitude that any sexual relationship between a physician and his patient will be considered an act of exploitation on the part of the physician; the burden of proving otherwise is always on the physician.

The authors are with the Institute of Mental Health Sciences, Rutgers Medical School, University Heights, Piscataway, N.J. 08854, where Dr. Siassi is Director of Adult Services and Associate Professor of Psychiatry and Dr. Thomas is Assistant Professor of Psychiatry.

The taboo against sexual relations between a physician and his patient is based more on pragmatic than on moral grounds. The medical model presumes a high degree of objectivity in the diagnosis, treatment, and prevention of illness. Moreover, the physician's task of helping the patient achieve health and well-being is facilitated by the establishment of rapport, i.e., a harmonious, nonthreatening relationship in which the physician is both an empathic participant and a dispassionate observer. It is the recognition that emotional involvement impairs the physician's judgment that prompts him to avoid treating the people in his life with whom he has strong emotional ties (his immediate family, for example). Any sexual involvement with the patient would also greatly impair a professional relationship that requires empathy and objectivity.

Even the most fervent advocates of total sexual freedom recognize the difficulties of a sexual relationship between nonequals. In the physician-patient relationship, the patient is often helpless and always dependent; a sexual liaison in such a situation has all the earmarks of exploitation. However, the authority and the prerogatives bestowed by society on the physician are in part predicated on the implicit trust that the physician will not engage in exploitation. Both the physician and society depend strongly on such trust—the physician in order to function effectively and society in order to rest easy about having invested so much power in one of its members.

This mutual interdependence makes the physician's position both delicate and precarious. This is all the more true in a democratic society where power is viewed with suspicion and distrust. The physician actually functions, as it were, in a fishbowl; it is only the public's belief in his trustworthiness and integrity that allows him the degree of freedom from the controls that a democratic society always puts on people in positions of power.

Whether or not some physicians betray this trust and engage their patients sexually should not affect the issue. Physicians are human and prone to human error. What is at issue is the shortsighted and destructive efforts of some physicians and nonphysicians to justify this error and even to seek some saving grace by ascribing "therapeutic benefits" to these relationships.

The consensus among students of society from Durkheim to Parsons is that society brings punitive sanctions against those who threaten its social cohesion. As long as the nuclear family continues to be the basic unit of society, taboos against incest will remain strong. It is equally probable that, as long as the physician-patient relationship exists, taboos against sexual liaisons between physician and patient will continue. To equate a sexual relationship between a physician and his patient with the other aspects of sexual freedom betrays ignorance of the basic tenets of society. The only comparable case is incest.

Hippocrates' admonitions of 2,000 years ago still hold. It is no wonder that the neophyte physician even now is called upon to take the oath: "Every house I shall enter for the sake of my patient's well-being, refraining from every intentional harm and all seduction, especially from love relationships with women or with men, be they free or bonded."

Making Abortion Consultation Therapeutic

BY CORNELIA MORRISON FRIEDMAN, M.D.

The author presents an approach to psychiatric consultation before abortion that attempts to determine the extent of the woman's ambivalence about the abortion by clarifying any unconscious motivations or conflicts. Other goals are an evaluation of the woman's capacity to cope and an assessment of the quality of life that would be available to the infant.

THE PSYCHIATRIC COMMUNITY has for the most part responded favorably to the Supreme Court decision removing first-trimester abortion from state jurisdiction. Psychiatric consultation before abortion will now be used at the surgeon's discretion and will probably be limited to the severely ambivalent woman, the young teenager, and the emotionally vulnerable woman with previous psychiatric problems. This paper presents a systematic approach to such a consultation and is designed to promote its therapeutic value.

Dr. Friedman is Clinical Instructor in Psychiatry at Harvard Medical School. Address reprint requests to 25 Chestnut Hill Rd., Chestnut Hill, Mass. 02167.

Psychiatrists have long felt that the abortion decision belongs to the woman (1–5). The previous requirement of a psychiatric diagnosis to justify abortion placed the psychiatrist in an uncomfortable position. Studies have shown that the traditional grounds for therapeutic abortion, such as schizophrenia (6), postpartum psychosis (7), and suicidal ideation (8), are not valid since women with these conditions show no demonstrably greater difficulty coping with unwanted pregnancy than do other women. Therefore, if one were a purist it would have been difficult to state that any mental condition really *required* abortion. On the other hand, fears that abortion in and of itself causes severe psychic sequelae have proved unfounded. Most women tolerate the stress of abortion as they do the other traumas of life—that is, with upset feelings but without emotional disability.

What I want to say is not new. Careful psychiatric consultation was mentioned frequently in Calderone's summary of the 1955 Planned Parenthood Federation Conference on Abortion (9). Rosen, in his book *Therapeutic Abortion*, published in 1954 and recently republished (10), described the complexities of some abortion consultations. As Calderone's book stated, "There are conflicting drives and it is so many units on one side that we cannot measure and so many units on the other side that again we are not able to measure; and that is seen in every aspect of this material" (9, p. 124).

My case material is drawn from several hundred abortion consultations. These were done in private practice; at the Harvard Community Health Plan, a prepaid health maintenance organization serving a heterogeneous working-class population; and at Boston Hospital for Women, where women of all racial backgrounds and of low socioeconomic status were seen. In addition, consultations at the Crittenton Home in Boston provided case material from patients who were approved for abortion but who decided instead to have their babies.

THE GOALS OF THE CONSULTATION

I will discuss the psychiatric interview as a potentially therapeutic experience for certain women. The interview focuses on: 1) the woman's ambivalence, 2) her capacity to cope, and 3) the quality of life available to the infant. The focus of my discussion is conflictual situations that have been uncovered in consultation for abortion; an assessment of the woman's ambivalence is easier after clarifying any unconscious conflicts that have resulted in exposure to pregnancy and conception. The emotional conflicts associated with unwanted pregnancy are diverse and complex, and experience with a wide range of women seeking abortion has revealed no single way to characterize them. Previous studies concentrating on a single dynamic or personality constellation have perhaps been limited by a too homogeneous patient population.

The major goal of the psychiatric consultation is to determine the extent of the woman's ambivalence about the abortion. Is the woman convinced that she does not want to have this child? In weighing her ambivalence, it is important to clarify with the woman any unconscious motivation for the pregnancy. A decision to bear a child is based ideally on a woman's mature longing for the child, her capacity for motherly giving, and adequate reality supports. Discussion of unconscious motivations gives the woman a clearer perspective of her inner and outer reality. She is then more free to make her decision on the basis of her mature feelings and her realities.

A secondary goal is the evaluation of the woman's capacity to cope with the pregnancy or abortion. Ekblad (11), in his study of 479 women, found that the only patients with severe emotional sequelae to the abortion were ones who had considerable emotional difficulty earlier. He pointed out that the real irony of abortion laws lay in the fact that "the greater the psychiatric indications for legal abortion are, the greater will be the risk of unfavorable psychic sequelae after the operation." Ekblad found undesirable sequelae in 11 percent of the 479 women and Sim (7) in four percent of 213 women. Expressing concern about these women, Sim stated, "The only proper role for the psychiatrist, should abortion become legal, would be to help decide who should *not* be aborted."

Women who are vulnerable are not difficult to detect for they usually have a psychiatric history and their management is not easy. Either continuing the pregnancy or having an abortion would be stressful. In the past psychiatrists have tended to assume that a continued pregnancy is less difficult than an abortion. However, we must learn more about this vulnerable group before conclusions can be drawn. (I anticipate more careful studies of women with maladaptive responses to abortion now that researchers are no longer occupied with proving that most women respond adaptively.) In the last analysis, it may not be the extent of psychopathology that causes difficulty for a woman but rather her inability to choose the abortion without marked ambivalence.

Another goal of the interview is the estimation of the quality of life available to the infant if he is born. Forssman and Thuwe (12) have demonstrated the increased difficulties for illegitimate and unwanted children. Raven (13) and others have pointed to the high incidence of unwantedness among battered infants and babies who died of crib death.

During the consultation I make two basic assumptions: 1) that a biologically mature woman will naturally seek sexual gratification and 2) that contraceptive information and devices are sufficiently available that the average woman can prevent pregnancy. Genuine contraceptive failure is occasionally encountered—for example, pregnancy with an intrauterine device in place. However, in my experience, the far greater number of unwanted pregnancies result from irregular use of contraceptives. For example, one hears fairly often of pregnancy occurring while a woman is switching from the pill to another form of contraception. Upon inquiry, one usually learns that the couple used no contraception at all during the interim.

So I ask: Why is this woman pregnant? I organize the search for the answer to this question around the

woman's relationship with her sexual partner. The resulting focus is helpful, since a person's capacity to form a stable, intimate relationship is the culmination of complex ego functions. The use of this focus tends to group individuals who are similar in their stability, capacity for feeling, sexual adjustment, resolution of dependence-independence conflicts, and tolerance for narcissistic frustrations. However, as with any system of psychiatric categorization, its very conception immediately provokes thoughts of exception.

UNWANTED PREGNANCY IN A STABLE MARRIAGE

A married woman seeking an abortion who has a viable, satisfying relationship with her husband may be struggling with the following conflicts:

1. Ambivalence about taking a more active, independent stance in life. Such a woman is often middle-aged, with higher education and some ambitions for herself. She is an organized individual, with a family of the size she planned. Her children are in school and are investing more of their energies outside the home. The woman may have made some efforts to seek employment or further education and felt vaguely anxious. Uncharacteristic laxness or memory lapse regarding contraception has resulted in pregnancy. The pregnancy protects her from her unconsciously feared independence but is consciously rejected because her family is complete. This woman is often surprised and irritated with herself.

2. Ambivalence about giving up the nurturant intimacy with an infant. This young woman's "last" child is a toddler, but she has special feelings about "having a baby in the house." She is well adjusted, but close scrutiny reveals her deeper investment in the current infant of the family than in the more mature members of the household, including her husband.

3. Fear of aging or loss of femininity by ending the childbearing period. I recall a woman of mature years whose family was complete. Through uncharacteristic laxness with contraception, she had become pregnant in the premenopausal period. This was her 11th pregnancy; she had eight children. She loved children and said that if she were only younger, she would like to have this child and even more. Although it was not true in this case, a woman with a premenopausal pregnancy will often have been uncertain about her femininity earlier in her life. There may have been conscious fears of childlessness or some realistic threat to childbearing. She may desire to carry this pregnancy to term but be embarrassed about what her older children or friends will think of her middle-aged motherhood.

4. Religious conflicts. These are seen in women who no longer practice their faith but remain tied to it by guilt. This was clearly the dynamic in a former Roman Catholic who was married outside the church and who, in a panic, sought consultation for an abortion. She used contraceptives regularly but had forgotten to take her pill while she was visiting her parents for the weekend. Her guilt and fear of punishment were evident in her panic.

5. Ambivalent competitive or grandiose fantasies about family size—e.g., a woman who has unwittingly channeled much ambitious striving into reproduction. She has tended to deny the considerable responsibility of each additional child. However, as time goes on, the rigors of motherhood may provide too little satisfaction and her denial may break suddenly after another pregnancy begins.

In most of these situations the woman is partially or completely aware of her emotional conflict. Often the pregnancy forces introspection and gradual awareness. In these cases the psychiatric consultation clarifies the woman's awareness and gives her an ally in mobilizing her strengths to resolve the ambivalence or conflict. Clearly, the husband's feelings about the pregnancy are an important consideration. Occasionally a husband will want another baby as proof of his continuing virility when a wife would prefer abortion. In my experience husbands or lovers attend abortion consultations only infrequently—about five percent of the time. The man's feelings are always discussed in these consultations. One may hope that now that the goal of the interview is no longer obtaining consent via establishing a psychopathological diagnosis, men will more frequently request and be requested to take part.

UNWANTED PREGNANCY IN TROUBLED MARRIAGES

Unwanted pregnancies occurring in married women with troubled relationships with their husbands tend to be associated with the following situations:

1. Intense conflict about divorce that the woman seeks to settle by impulsive action rather than anxiety-laden confrontation. I have seen several cases in which the unwanted pregnancy occurred just as the woman's desire for separation was crystallizing.

2. Stressful unwanted pregnancy in an improving marriage involving a markedly masochistic woman. One woman became pregnant after she had stopped taking the pill and was waiting for an appointment for a new contraceptive. This woman had three children, born during a previous long, unhappy marriage. She had been remarried for a year and was able to return to college since her children were old enough for school. Her adjustment to her second marriage was initially difficult, and she raged at her new husband for not solving all her problems. However, he took it calmly and eventually she stopped storming and had her first prolonged period of stability in ten years. She was furious at the untimely pregnancy, which threatened her new-found enjoyment in living.

3. Expression of anger at the husband for his absence, heavy drinking, or other behavior that is seen as his lack of caring. While this anger may have some realistic basis, it is often related to some expectations in the woman for parental care. Under this category I would include the women recently described by Biele (14) as having "depressive practices." Biele described a personality constellation including vindictiveness, manipulativeness, and anxiety. When the woman's covert maneuvers to control

fail, she resorts to exposure to pregnancy as an expression of her anger and anxiety.

In the above situations the psychiatrist must evaluate both the stability of the woman and the state of the marriage, and consider referral for individual or couple therapy. There is a tendency for women in this group to have more psychopathology—i.e., graver conflicts about passivity, greater dependence, deeper sadomasochistic tendencies, and deeper pregenital longings. Often referral for marital counseling or psychotherapy is indicated but seems pointless because the woman resists treatment. A clear statement about the problem may nevertheless be heard by the woman and stored for future reflection.

ILLEGITIMATE PREGNANCY FEATURING A RELATIONSHIP WITH THE MAN

Illegitimate pregnancies occur in women who have full relationships with the father of the baby and women who have no relationship at all. When a real relationship exists many of the previously mentioned issues will be seen. In addition, the psychiatrist may see:

1. Markedly dependent or sadomasochistic relationships, in which the woman deliberately conceives to force a marriage. If the man refuses, the woman often is left with little desire for the child. Evaluation of the woman's attitude toward abortion is crucial. She is struggling with rage at the man for abandoning her. If she views abortion as a murderous act, she may see it masochistically; that is, she will hurt herself to show the man how bad he is. Once the abortion is performed, her guilt about her rage and the death of the fetus, as well as her inevitable frustration about the relationship, can cause a severe state of turmoil. Detection and discussion of this motivation before any decision may reduce subsequent guilt and turmoil.

2. Angry rebellion in a teenager who wishes to marry a boy forbidden by her parents. The girl has assumed that her parents will consent to her marriage when they are confronted with a pregnancy. Often she does not want an abortion, seeks it only after coercion by her parents, and refuses it when given the option. Such a girl's rebellion against her parents prevents her accepting the abortion; she chooses instead the physical rebuke of a growing abdomen. These cases can be incredibly complex. Careful questioning about the parents' disciplinary methods usually reveals wide swings between permissiveness and harsh, rigid control. A referral to a maternity home with an active social work staff sometimes achieves good results. The emotional pressures of the pregnancy force recalcitrant families to reconsider their embittered positions.

3. The appearance of a series of real relationships with men, resulting in a series of pregnancies and abortions. Often the men are of different racial or ethnic backgrounds. These girls have severe hysterical character problems, with strong depressive elements. They are searching for something from their fathers in these relationships; that something is partly sexual but more largely something involving closeness and nurture. The pregnancy is desired, so contraception is faulty; the pregnancy is forbidden because of its oedipal association, and abortion follows. This is a complex pattern, and it requires insight-oriented psychotherapy in order to effect any change.

ILLEGITIMATE PREGNANCY WITH NO RELATIONSHIP WITH THE MAN

Finally, psychiatrists see women who have no lasting relationship with the father of the baby. This group tends to be the youngest and most disturbed of the groups discussed and includes the following:

1. Women with physical defects (usually congenital), abdominal operations, or recent miscarriages who are concerned about their ability to be normal. These women equate normalcy with reproducing. A recently married woman illustrates this dynamic nicely but defies my system of classification because she maintained a fairly good relationship with her husband. She had had a severe episode of gonococcal endometritis and was told that she had been treated just in time to save her fertility. Vague concerns about this at the time turned after her marriage into a persistent fear that she might be unable to conceive. Her birth control method had for several years been a risky combination of rhythm and condoms. It is interesting to note in passing that her method failed her only in this emotional setting.

2. Women whose sense of themselves is failing. Heroin addicts or borderline psychotics may become pregnant in a desperate attempt for integration. Obviously, to approve an abortion for such a woman without providing good psychiatric care is to miss the point; this group is highly vulnerable.

3. Young, deprived, and delinquent teenagers who actively seek pregnancy to have something to love. I am referring to girls like Gedo's (15) patient, who revealed in analysis that her illegitimate pregnancy was in part "an attempt to fill a sense of inner emptiness and depression." Gedo noted that his patient insisted on incorporation of an object or nothing at all. Often such a girl does not desire an abortion, but accepts it on the advice of a therapist who starts to give her the affection she so craves.

4. The highly narcissistic, rather grandiose young woman who decides to have a baby just because she wants one and is not in the least embarrassed to describe her motivation in this way. This group is small in number; the woman usually does not follow through with the abortion even if it is approved. She likes the father of the baby well enough, but cares little whether he stays with her because her primary investment is in herself. She has fantasies about the gratifications of the mother-child relationship and sees no point in postponing them.

CONCLUSIONS

I have presented an approach to psychiatric consultation before abortion to maximize the therapeutic poten-

tial of the experience. The primary goal of this consultation is to determine the extent of the woman's ambivalence about the abortion. In order to do this, the consultant uncovers and clarifies any unconscious motivation or conflict, helping the woman to obtain a truer perspective of her inner and outer reality. A second goal is the evaluation of the woman's coping capacity; there is evidence that the small number of women with marked post-abortion emotional sequelae have been unstable previously. Such women clearly need good supportive follow-up if abortion is chosen. A third goal of the consultation is the assessment of the quality of life that would be available to the infant.

I have described a number of conflictual situations associated with unwanted pregnancy. In these situations, the conflicts are diverse and the woman's feelings and relationships are complex. It will require an experienced, skilled, and insightful evaluator to sort through some of these situations. In clinical situations where there is no routine psychiatric screening, it is important for personnel to learn through experience which women require psychiatric consultation or aftercare. In addition, recommendations for further therapy must be tailored to the individual.

Foremost in the interview is the discussion with the woman of the unconscious and conscious determinants of her pregnancy. She needs to know whether the pregnancy is a genuine accident or the expression of some hidden wish or fear. Knowing this, she can more realistically appraise her life situation and her capacity to care for an infant. The tragedy of past abortion laws was that they provoked women to struggle with false issues. Feeling that abortion might be denied, the woman panicked and concentrated on obtaining the abortion. The real human issues for a woman with an unplanned pregnancy are her mature longing for a child, her present capacity to love and give, her present reality, and a weighing of her morality.

Marriage, Family, and Parenthood

BY HENRY GREENBAUM, M.D.

The author discusses the recent attacks against marriage, family, and parenthood by some of the leaders of the Women's Liberation Movement. He points out that the difficulties that cause human suffering in these institutions are not intrinsic to them but are determined by the quality of the people involved in them. He believes there is a deep human need for marriage, family, and parenthood, which has its roots in the prolonged biological and psychological dependency of the human child. The conditions of personality development necessary for successful functioning in marriage, family, and parenthood are analyzed.

MARRIAGE, family, and parenthood have recently come under attack by some extremist leaders and writers of the Women's Liberation Movement. The alternatives they propose are fuzzy and bear the earmarks of instant solutions to complex biological, psychological, and social problems. No doubt the social institutions of marriage, family, and parenthood have frequently been the cause of much human abuse and suffering, but the remedies offered amount to throwing out the baby with the bath water.

I believe the women's drive for equal rights is morally, politically, and historically justified and constitutes a progressive force in society. Nevertheless, some aspects of it do elicit criticism. Some feminists appear to believe that there are magical effects in destroying institutions that have developed by trial and error over thousands of years of social evolution. Barbara Balogun (1) said about marriage:

> I feel that the personal relationships of marriage must undergo a revolution ... the roles of male and female must be completely redefined—*no, eliminated.* I do not see this as possible in the present relationships of marriage.... The only alternative, as I see it, is communal living.... I also recognize that, conditions being what they are at the present time, most men feel so secure in their oppressive role that they will not give up their power willingly. Therefore, male-female communes will be impossible to establish. *It may be that our only solution will be the dissolution of marriage, with the foundation of all-female communes to eliminate the burdens placed on women* (pp. 293–295; italics mine).

Linda Gordon (2) has also written against the family: "Families perpetuate themselves and their bad values by educating children to see them as the only model for adult life.... *The nuclear family must be destroyed, and people must find better ways of living together*" (p. 187; italics mine). Simone de Beauvoir (3) saw no satisfaction in marriage and motherhood:

> The tragedy of marriage is not that it fails to assure woman the promised happiness ... but that it mutilates her; it dooms her to repetition and routine.... At twenty or thereabouts mistress of a home, bound permanently to a man, a child in her arms, she stands with her life virtually finished forever. Real activities, real work, are the prerogative of her man: she has mere things to occupy her which are sometimes tiring but never fully satisfying (p. 478).

These are but a few examples of feminist attitudes toward marriage, family, and motherhood. Until now man, overtly or covertly, has downgraded these institutions. Until now male-shaped society downgraded women who were not married or did not have a family. Now, if the feminists have their way, women who marry and have children will be downgraded and condemned as inferior beings.

William V. Shannon (4) described succinctly the attitude of many feminists:

> It is the function of advanced groups like the professional feminists to articulate what is only implicit in the behavior of a much larger group. That is the inner logic of their downgrading of woman's biological role, their angry depreciation of motherhood, their insistence on every mother's right to park her baby in a daycare center and hurry off to work even when financial circumstances do not require her to do so.

So we see it has happened again; history is repeating itself. An oppressed social group is raising its voice in protest against the oppressor and in the process it is identifying with the values and methods of the oppressor. This was the case with the French Revolution, which overthrew the despotism of absolute monarchy in 1789 only to replace it with the despotism of terror. It was also the case with the Russian Bolsheviks, whose tyranny equaled the tyranny of the czar they overthrew in 1917. In recent years in America some black leaders have adopted separatism as an instrument for liberating their people. And now the Women's Lib Movement seems to be following suit. I think some feminist attitudes reflect a harshness, intolerance, and self-righteousness that antagonize even their friends.

The Redstockings Manifesto (July 7, 1969) provides an example of this (5): "Women's submission is not the result of brainwashing, stupidity or mental illness but of

Dr. Greenbaum is Associate Clinical Professor of Psychiatry, New York University School of Medicine, New York, N.Y. His address is 65 Tennis Place, Forest Hills, N.Y. 11375.

continual daily pressure from men. *We do not need to change ourselves*, but to change men" (p. 110; italics mine).

It seems logical that, to improve the quality of life and to create equality and harmony between men and women, both have to change radically. Before we destroy existing institutions, we ought to remember that, just as men and women abuse and exploit each other in marriage, they may do the same thing in a commune. And if certain men and women as parents are unkind and cruel to their own children, what assurance is there that workers in daycare centers will not be even more cruel to the children in these centers?

THE QUALITY OF INSTITUTIONS

Of course no social institution should be held sacred. Social institutions have a raison d'être only if they serve men, women, and children by enhancing their security and their happiness through self-realization. For example, the institutions of slavery, feudalism, prostitution, war, and the like are based on exploitation and oppression of man by man; although they have been the products of historical necessity, they no longer serve modern man and are therefore obsolete. Even the institutions of capitalism and communism are questionable as far as man's long-range needs and the survival of civilization are concerned. Too many elements that can oppress the individual are built into these systems.

The institutions of marriage, family, and parenthood on the other hand are a different story. Inequality of spouses, exploitation of one another, and the mistreatment of children are possible in these institutions but are not intrinsic to them. The quality of these institutions is determined by the quality of husbands and wives, of mothers and fathers, as people. Mature people are able to make of these institutions a source of strength and satisfaction for both the individual and society. No wonder Lidz (6) wrote:

> A larger proportion of the population is married than ever before. It appears as if people living in an insecure world in which values and purposes are obscure have intuitively realized that meaningful values can be found in the relationships between spouses and between parents and children.... Despite the inevitable frustrations and even despite tangible failures, the vast majority of persons seek a more enduring happiness in firm family relationships.

When Linda Gordon (2) wrote that "the break-up of the families *now* is an objectively revolutionary process" and "the women's liberation movement should support and encourage women and young people who are leaving parents, leaving husbands, trying to avoid marriage and/or pregnancy," she demonstrated a lack of understanding of a deep human need for marriage, family, and parenthood. This need has its roots in the prolonged biological and psychological dependency of the human child. The dependency, which lasts about 18 years, brings the growing child into intimate relationship with his parents, and this has a humanizing, civilizing, and socializing effect upon the child. It imprints on him psychic qualities that no other species has developed—namely, a need for enduring love (both to love and to be loved); intimacy; interdependence; loyalty and devotion; commitment and responsibility; security against loneliness in time of illness, old age, or other existential crises; and stability.

Sex is not one of the basic reasons for marriage, because sexual satisfaction can be obtained outside of marriage. However, sexual love is an important vehicle for the fulfillment of the above-mentioned needs for marriage and marriage in its turn becomes an effective vehicle for sexual expression.

There is a widespread misconception that romantic love cannot endure in a long-lasting marriage. It is true that men and women can be biologically attracted to people other than their spouses and that this can be a disrupting factor in marriage. However, psychosexual maturity enables both men and women to integrate extramarital sexual stimuli and redirect them toward their spouses, in the same way that hostile stimuli can be redirected from one person to another. It therefore seems to me that mature spouses who are in love with each other and who have a desire to please each other can consummate their sexuality in a very satisfactory and mutually enriching way throughout an enduring marriage.

CAPACITY FOR INTIMACY

In order to function successfully in marriage, a person must have successfully gone through the different stages of personality development and reached the stage that Erikson calls intimacy. But it is only after the previous stages, described by Erikson as basic trust, autonomy, initiative, industry, and identity, have been successfully established that real intimacy is possible. "Intimacy," Erikson wrote (7), "is really the ability to fuse your identity with somebody else's without fear that you're going to lose something yourself. It is this *development of intimacy which makes marriage possible as a chosen bond. When this has not developed marriage is meaningless* (p. 48; italics mine).

Erikson differentiated between real intimacy, which is characterized by a genuine capacity for love, affection, friendship, and sexual tenderness, and the pseudo-intimacy of the earlier stages of adolescence. People with a sense of pseudo-intimacy fail in marriage and shy away from parenthood because they have not reached in personality development the stage of generativity, which enables an individual to "care for" somebody or something and to "take care of" that which needs protection and attention:

> The principal thing is to realize that this [generativity] is a stage of the growth of the healthy personality and that where such enrichment fails altogether, regression from *generativity* to an obsessive need for *pseudo-intimacy* takes place, often with a pervading sense of stagnation and interpersonal impoverishment (8, p. 97).

It is widely accepted that children need loving parents in a loving environment to develop a healthy personality. However, it is less widely recognized that adults, both men and women, have a need to rear children in order to enhance their own self-realization and to achieve fulfillment of some of their emotional, mental, and social aspirations. Therese Benedek (9) wrote: "The child represents not only the parent's self as a child but also, or more so, his hope and expectations of self-realization through the child. Parents and children strive toward this goal through the unconscious process of reciprocal introjections and identifications" (p. 400). In discussing the relationship between the adult child and the aged parent, Benedek (10) wrote:

> As once the parent was the need-fulfilling object of the child, now that "adult child" is the need-fulfilling object of the aged parent. . . . Originating in the instinct for survival in the offspring, parenthood establishes a sense of identity that integrates the biologic and social functions of the personality (p. 205).

Although there are those who, because of realistic or intrapsychic reasons, do not become parents, it is important to recognize that parenthood is a natural phase in the healthy adult (8–11). Anthony and Benedek (12) wrote: "Parenthood is a manifestation of 'natural man' and, as such, is governed by the laws of biologic processes that are universal."

THE FUNCTIONS OF PARENTHOOD

The complexities of parenthood are immense. Suffice it to say that it can be a source of great joy and happiness as well as of anguish and turmoil of a nature probably little known in other phases of life. It can mobilize feelings of altruism, devotion, and commitment and a sense of responsibility toward offspring that are only rarely observed in nonparenthood situations in people who have a special gift for dedication to high altruistic ideals or to artistic creativity.

Parenthood represents for many people a hedge against loneliness and the existential insecurity of old age and infirmity. It also fulfills to some degree the wish for immortality and it provides the individual with another chance to relive his own childhood and adolescence, with the opportunity to master some of his past traumatic experiences. For instance, one of my patients, who was taken to a concentration camp at the age of ten and survived without her parents, felt that the opportunity to care for her own daughter was of great help to her in overcoming the painful effects of the deprivation of mothering in her own childhood. Thus we can say that mothering promotes growth and has a humanizing effect on both mother and child.

As we see, parenthood is an important stage and child rearing is an important function in the life of the adult. To downgrade them is to ignore deep human psychological needs. Germaine Greer (13) presents a case in point. Lacking experience in matters of family and parenthood, she has stated authoritatively: "Those families in which the parents replace themselves in two children are not the most desirable ones for children to grow up in" (p. 231). Psychoanalytic experience seems to contradict this view. Lidz (6), for example, wrote:

> The isolated nuclear family structure that has developed through industrialization and urbanization is better suited than the extended kinship family for training its offspring for the adaptability required in a rapidly changing world. . . . Its stability and capabilities depend primarily upon the personalities of the spouses who unite to form the family.

Germaine Greer (13) believes that a woman who has a child is not automatically committed to bringing it up and that a group of children can be more successfully reared by one or two hired women than by a "bored and imposed upon" mother. (The mother is ipso facto the villain—bored and imposed upon.) True to her beliefs, it is her plan, when she has a child, to have it brought up with other children by an Italian family living in a farmhouse, without letting the child know she is his "womb-mother," so that she can also have relationships with other children. This is absurd. Psychoanalysts who treat adopted children know how often they are tormented and disturbed by the question of why their biological mothers abandoned them.

After downgrading family and motherhood, the logical thing to do for certain feminists is to recommend institutional care of children. Hence the campaign for children's daycare centers. There is no doubt that mothers of small children who must or prefer to work should have access to the services of high-quality day centers. But I believe that the Women's Liberation Movement would make a greater contribution to society's well-being if it demanded that parents of small children receive sufficient welfare assistance to be able to rear them themselves if they so desire. And if both parents work, they should be entitled by law to paid part-time leaves of absence so that they may share in rearing their children.

Psychoanalytic experience shows that family care is preferable to institutional care. "To develop a child with a healthy personality," Erikson wrote (8, p. 98), "a parent must be a genuine person in a genuine milieu." I believe the family is the genuine milieu. It can be considered the cradle of mental health or mental illness and it is a social responsibility to preserve and upgrade the family. One could say that the quality of life and of our civilization depends on the quality of the family and the quality of parenthood.

It is noteworthy that 20,000 women responded to a questionnaire prepared by *McCall's* magazine (March 1971) on how women felt about issues raised by the Women's Liberation Movement. The majority (76 percent), regardless of age, felt that young children need a full-time mother.

I agree with Benjamin Spock's statement: "I myself would say it is much more creative to rear and shape the personality of a fine, live child than it is to work in an office or even to carve a statue." However, the modern woman is fortunate in that there is no need for her to

choose between the creativity of family life and the creativity of work. Both can be integrated in a system of values that become conflict-free guidelines for harmonious living. Madame Curie presents a good example of such integration. She was both a dedicated mother and a brilliant scientist.

CONCLUSIONS

As a psychoanalyst I am in deep sympathy with the Women's Liberation Movement. I believe that inequality between men and women prevents genuine love, friendship, and cooperation between them in marriage, family, and parenthood and thus frequently becomes a source of mental illness. Women have made great strides in their struggle for equality in the past half-century. Today, their emancipation is still far from complete and needs the wholehearted support of all men who aspire to a better quality of life. But I take exception to views on marriage, family, and parenthood that, if implemented, would lower the quality of life.

I do not claim to know which ultimate forms the relationship between men and women should take in order to assure a healthier humanity and a better quality of life. But whatever form our evolving institutions do take will depend to a great extent on our moral value systems and the quality of people.

Religious Delusions in Counter-Culture Patients

BY PERITZ LEVINSON, M.D.

Messianic delusions—until now rather rare and poorly understood—appear to be increasing in incidence and to be influenced by the values of the counter culture. The author identifies the principal clinical features of delusions: the belief in one's omnipotence and omniscience, the avoidance of affect-laden experiences and thoughts, the pursuit of asceticism, the experience of exalted mystical states, and the tendency to form symbiotic relationships that are devoid of meaningful emotional investment. The author discusses the treatment of this difficult problem and offers observations from his clinical experience.

RECENT TIMES have seen the rapid growth of counter cultures (1) among the youth of this country. The hippie movement gained many adherents; its recent dissolution has been followed by an array of subcultures such as religionists ("Jesus freaks"), naturalists ("environmental freaks"), occultists ("astrology freaks"), and others. The features that remain from the parent hippie culture are a rejection of the values of the establishment and a dedication to peace, purity, universal camaraderie, and the pursuit of pleasure. Drug use, long hair, and characteristic dress, music, and food have been widely adopted by people who are not in counter-culture groups.

Dr. Levinson is an Associate in Psychiatry at Mount Sinai School of Medicine, New York, N.Y. His address is 120 East 89th St., New York, N.Y. 10028.

The author would like to thank Lloyd H. Silverman, Ph.D., for his helpful comments during the preparation of this manuscript.

An abrupt increase in the incidence of religious delusions was noted among patients admitted to a general psychiatry service in a large city. In the cases that were selected for study, religious delusions were the central and dominant symptoms of the psychosis rather than inconsistent and minor features. Each of these patients was found to be strongly influenced by counter-culture factors. A review of the records from 1970 to 1972 yielded eight cases of persistent religious delusions, compared with only one case during the preceding two-year period and six cases out of 25,000 in the Michigan state hospital system in 1958 (2). The eight subjects, who were men between the ages of 18 and 26, were from 185 first admissions in this age and sex grouping. The delusions usually occurred as part of an acute schizophrenic process and involved the subject's identifying himself as Christ, believing he was on a messianic and prophetic mission, and believing he was able to communicate with beings of a higher order by means of hallucinations.

Each subject was found to clearly reflect counter-culture influences. Besides the outer trappings, this was manifested in the popularity of vegetarianism, Eastern religions, mysticism, meditation, and uncontrived approaches to relationships. Although other patients who were admitted during the two-year period reflected a variety of counter-culture influences, none exhibited clear-cut and persistent religious delusions. Instead, these patients presented more traditional symptoms, such as depression, confusion, and paranoid thinking. Our eight subjects were studied intensively for the psychodynamic determinants of the religious delusions, the influence of the counter culture, and the unique ways in which these patients coped with stress.

PRINCIPAL CLINICAL FEATURES

Each subject was admitted to the hospital with the grandiose religious delusion that he was "Jesus Christ," "the son of God," or "the Messiah." The patient's identification with Christ generally reflected an accepted religious belief, but there was some variation in this. For example, the delusion often included the conviction that he had the power to control people's minds, to read the minds of others, or to cure illness. This control of others would render them submissive followers; the patient often read into the casual glances of others unusual significance such as acquiescence, deep understanding, and silent adoration. In addition the patient believed he could put people "in touch with their feelings," make them able "to discover real truth," and "liberate" them. The messianic claim sometimes included the conviction of having achieved Nirvana and of being able to lead others to this prized state of exaltation. One patient had written a 1,700-page volume of "truths," which he regarded as a new Bible.

Along with these narcissistic elements, these patients were generally withdrawn, intellectualizing, and overly controlled individuals who carefully avoided affect-laden experiences. Their life-style featured ambivalence, doubting, isolation, and rigidity. Denial was often used as a defense; paranoid elements were present though not prominent. One might expect a heightened level of aggressivity in these patients because of the harsh and rejecting attitudes of their parents, separation in their early years, frequent outbursts of anger, their characteristic defenses, and psychological test results. Examinations for neurological disorders revealed no problems.

Homosexual behavior was not a factor in these patients. Meaningful heterosexual relationships were limited by the pursuit of asceticism, the avoidance of affect, and pathological egocentrism. These subjects formed a special type of relationship that was both symbiotic in nature and devoid of meaningful affect. Their need for the object was clearly evident in their desperate attempts to restore an aborted relationship but they either used and dominated the partner or became the passive member themselves, either of which leads to an empty dyadic situation. At times the subject alternated between feeling omnipotent and servile.

In studying these patients, we found four areas that revealed important information on how they coped with stress: 1) the relationship of the religious delusions to their defenses, 2) the influence of the counter culture, 3) the role of meditation, and 4) the meaning of the symbiotic phenomena found in these cases.

RELIGIOUS DELUSIONS AND DEFENSES

Freud (3) and later clinicians (4–6) identified hostility and rivalry as central features of the religious delusions of their patients. Rokeach (2) and recently Perry (7) found that patients with religious delusions were searching for support, protection, a stable identity, and a sense of power. Although our subjects exhibited all these features, we found that their struggle against aggressive urges was paramount. These patients were aided in their struggle by an identification with Christ, who they believed had accomplished a superhuman transcendence over man's baser impulses, including a mastery of sexual impulses that was necessary to maintain asceticism. Our patients' image of Christ's stoicism, serenity, and indifference to pain and discomfort aided their repression and isolation; Jesus' practice of forgiving his tormentors strengthened their reaction formation.

The passive-aggressive and defiant images of Christ are other important features that aided our subjects in coping with their aggressive urges. In the final struggle, Jesus presented the image of a powerful and aggressive leader who made a vigorous assault on the establishment. An identification with Christ gave our patients a sense of omnipotence. This is not to overlook other possible reasons for the identification with Christ, such as the need to deny a sexual relationship between their parents and the desire to recreate a father-son relationship. The latter was observed in certain subjects whose identification with Christ's obedience to God was a solution to oedipal conflict and a defense against aggressive urges. However, pregenital features were foremost in our cases, which

would explain why the delusional states invariably followed separation or the threat of separation.

Case 1. A 23-year-old man, quiet, withdrawn, and bearded, became psychotic after leaving home to accept a prized graduate school fellowship at a distant university. His mother had encouraged the move to fulfill her own ambitions. The patient had been raised by a punitive father, now deceased, and a rejecting mother. He had been lonely and withdrawn and clung to his mother.

Upon taking up his new position away from home, the patient felt isolated, abandoned, and rejected. He was aware of a painful longing for home and of strong feelings of hostility toward his mother for having permitted him to go. He submitted a grandiose proposal for a thesis that would "change the world." He was aware of mounting anger, frustration, agitation, and confusion. He began to have the delusion that he was Christ and that he had a prophetic mission to save people. The identification with Christ brought about a state of relaxation and a sense of power, serenity, and identity that were clearly evident upon his admission to the hospital.

INFLUENCE OF THE COUNTER CULTURE

Cultural factors facilitated both the denial and the expression of aggression in these patients, partly through the externalization and displacement of anger onto the establishment. Rejecting society's traditions also led to expressions of passive-aggressive and defiant impulses, of which drug use was only one example. On the other hand, the philosophy of peace and nonviolence strengthened reaction formation in those of our patients who were struggling against aggressive urges. The patients' involvement in Eastern religions added to this and supported obsessive defenses, while the practice of Yoga, Zen, and vegetarianism provided needed compulsive mechanisms and a sense of control and mastery; meditation furthered these ends. In some situations "soft" drugs were used to aid the ego in modulating affect, regulating drives, aiding self-esteem, and promoting socialization. Hallucinogens were generally shunned because of the fear of losing control. Although our subjects received support from the amorphous, accepting, and nondemanding counter culture, they were also threatened by the lack of controls and the fleeting relationships in this hedonistic society. These comments touch only the high points of what is actually a complex cultural phenomenon with a myriad of influences upon its members.

Case 2. A 19-year-old was admitted in an acute schizophrenic state that was marked by withdrawal, a preoccupation with religion, and compulsive meditation. The patient had been abandoned by a girl with whom he had established a crucial symbiotic relationship. He then joined a nearby hippie group and began to use marijuana to "block out reality" and to raise his self-esteem. Heavy marijuana use enabled him to "cool it" in the face of mounting anger at the rejection. He took part in political activity and peace marches and showed extreme bitterness toward the government. These measures were insufficient to stem a growing sense of losing control, and the patient began to sit in the lotus position continuously in an effort to control all thoughts and impulses, as well as grunts, coughs, belches, and flatus. He refused to eat and was hospitalized.

When he did not respond to treatment with tranquilizers, the staff stopped the patient from meditating. This resulted in explosive and violent behavior that ceased only when he was permitted to resume his meditation position and exercises. In the following days, the religious delusions gained predominance as the use of meditation decreased.

THE ROLE OF MEDITATION

All of our patients had more than a casual interest in meditation; five had practiced it frequently for varying periods of time in response to stress. Meditation aided such ego functions as perception and drive modulation, induced muscular relaxation, and limited their mental imagery, ideas, and specific sensory awareness. This modification of perception provided a barrier against distracting stimuli, such as threatening aggressive urges. Exercises concerned with the control of breathing and other motor functions added to the sense of mastery.

Four of the patients who engaged in meditation experienced mystical states that afforded a sense of omnipotence and grandeur and promoted a feeling of being merged with the universe in a kind of symbiotic or "oceanic" union. The concentration of attention on inner experiences by means of meditation and drugs reduced the patients' awareness of differences between the self, objects, and surroundings.

Case 3. A 24-year-old shaggy-haired, bearded, and withdrawn man had finally found a girlfriend, whom he treated in a superior, domineering, and controlling manner. Since his mother had abused and exploited him, he was determined not to be in a vulnerable position again. However, although he went along with the casual sexual behavior of the counter-culture group he belonged to, he was actually deeply hurt by his "wife's" occasional infidelity, which induced profound feelings of rejection and rage in him. As the relationship continued, the patient became subject to episodes of violent impulses, which he attempted to control with the frequent use of marijuana. To this he added regular periods of meditation, which he had previously practiced only sporadically. He moved with his girlfriend to a thinly settled area, where "she would be all mine" and where he could meditate without distraction. He enjoyed a feeling of being "at one with nature, the stars, and the cosmos," and had a mystical experience in which he felt merged and united with the universe. The isolated and untrammeled surroundings were untouched by reality and favored the development of grandiose fantasies that evolved into religious delusions with messianic content.

SYMBIOTIC AND MERGING PHENOMENA

Recent years have brought a growing conviction among investigators that a high level of activation of aggressivity is a major etiological factor in schizophrenia (8–11). At the same time, the important role of symbiotic relationships and merging phenomena in the schizophrenic's management of aggressive impulses has become fairly well recognized (10–13). Theoretically, the schizophrenic attempts to preserve the object of his ag-

gression by merging with it, but he must not go too far for fear of annihilation. This formulation accounts for the special symbiotic relationships that our patients formed. While they were symbiotic in nature, they were "hollow," since the patient's emotional involvement was limited. At the same time they were necessary to his existence since separation from the object of the relationship provoked panic; a desperate attempt to reestablish the symbiotic relationship with the object, a real substitute, or an imaginary one; and, finally, breakdown. The substitution of an imaginary person was important since the union with Christ represented the reestablishment of a close tie, but with an idealized person.

Case 4. A 20-year-old hippie was admitted to the hospital in an acute schizophrenic state that included the delusion of being Christ. His mother had suffered recurring depression and his father had been cold, aloof, and hypercritical. His only sibling was a shy, introverted brother, one year younger, whom the patient had dominated and intimidated throughout childhood. The patient had felt jealous of his younger brother and had often beaten him up, for which he felt a great deal of guilt. In adolescence he gained control over these violent impulses and formed a close attachment to the brother, who accepted his protective attitude with relief. The relationship was a symbiotic one, but there was very little genuine affective interaction.

The first separation occurred when the patient went away to college at age 18. He felt lonely, confused, and anxious and soon lost interest in school. He began to move within a counterculture group and became preoccupied with religion, mysticism, and drugs. Only when the patient returned home some months later did he focus his energies constructively and obtain a job.

The following September the younger brother went away to college and the patient once again became disorganized. He eventually joined his brother, roomed with him, audited his classes, and read with him in the library while the brother studied. The reestablishment of a close relationship caused the symptoms to disappear. A few months later the brother found a girlfriend and moved in with her. The patient soon felt a mounting fury and expressed the conviction that "the universe was coming apart." He developed the delusion that he was "Jesus Christ, the Messiah" and began to act accordingly. Although the patient's anger disappeared, his bizarre religious behavior led to his hospitalization.

SPECIAL TREATMENT CONSIDERATIONS

Three main factors have to be considered in planning treatment for these patients: 1) the problems of the acute schizophrenic episode, 2) the chronic schizoid and narcissistic personality, and 3) the symbiotic, emotionally empty relationships that these patients formed.

The acute schizophrenic symptoms generally respond to treatment with psychotropic drugs, especially the phenothiazines, although the response may be delayed. The goal of making the religious delusional system less rigid is important since compulsive activities, such as the continuous reading of Bibles, the recording of grandiose thoughts, and meditation, provide formidable resistances. The patient successfully avoids involvement with staff, other patients, and activities when he is in these states of preoccupation. On the other hand, one has to be careful in forcing the removal of such compulsive activities since they may be serving a vital function for a failing ego (14).

Once the patient is ready for expressive forms of therapy, both group and individual approaches are useful. The initial need is to deal with these patients' acute panic states and strong destructive impulses, as well as to establish rapport and trust, qualities that will be useful in the later attempt to repair the underlying chronic personality disorder. This attempt requires confrontation of the profound feelings of loneliness, inadequacy, frustration, and despair that the patient is trying desperately to avoid.

A frequent barrier to interaction with these patients is the demeanor of piety, saintliness, helplessness, and martyrdom that grows out of the religious delusion itself. The result is that the staff may feel guilty or sympathetic toward the patient, unknowingly show him the respect they would show a cleric, or shy away from the aggressive approach that is required to reach out to a seclusive patient and to set limits on a defiant one. In this way the staff lends reality to the patient's grandiose delusional system. The other patients quickly sense and resent the favoritism; they avoid the patient too. Their repressed anger may cause grotesque fantasies about "that withdrawn monk" or "homicidal patient," who usually ends up isolated in a private room.

The chronic personality disorders of these people are difficult to change since they often arise from defects in primitive ego functioning. Due both to the practical considerations of time and means and to the patient's limited capacity for relationships and frustration, it is wise to settle on realistic goals rather than "total cure." During the acute psychosis, these patients may be poorly motivated for therapy; once the acute symptoms are relieved they may be even less motivated. Basic realistic goals for therapy include helping the patient understand the precipitating factors of his illness (such as separation or drugs), making the patient aware of his strong destructive urges, and encouraging his continuing reliance on the therapist as an auxiliary ego, even if the treatment must proceed on an irregular basis because of the patient's frequent need to interrupt.

The symbiotic syndrome demonstrated by some of our patients requires special treatment. The symbiotic psychosis, as it occurs in adulthood, usually features a strong closeness and interaction with the object of the relationship and ambivalence toward it, both a need for and a fear of fusion, a fluctuating sense of differentiation, periods of withdrawal and isolation, and finally a regression to overt schizophrenia when separation occurs. Clinicians who have reported on the treatment of these cases (13, 15–17) have generally dealt with less regressed patients than ours. Limentani (13), for example, noted that his patients searched for a strong figure in reality (often the therapist) with whom to establish a new symbiotic identification upon separation from the object. Our patients accomplished this restoration with a delusional figure, Christ. The treatment methods used by other clinicians, which involve the restoration of the symbiosis in the course of the transference followed by its analysis and resolution, by "desymbiotizing" or by a "corrective

emotional experience," could not be directly applied to our subjects.

When our patients were in the "fixed" state of religious preoccupation, psychotropic medication was the treatment of choice. As they began to improve, this state was replaced by one of continued withdrawal and depression or by one of superficial amiability and conformity that masked an underlying distrust and denial of illness. These represented postsymbiotic "objectless" states and medication was less effective at this point. The high degree of emotional shallowness, intellectualization, grandiosity, and distrust of "the establishment," including doctors, also made a meaningful therapeutic relationship difficult to maintain. However, if the therapist and staff continue to provide needed ego functions, such as a sense of identity, impulse control, and support, while tenaciously attempting to prevent avoidance and withdrawal, patients often form new relationships. These are invariably with nonprofessional staff members or nurses, with whom the patient feels less inadequate and less threatened. These relationships clearly reflect the patient's psychopathology and come to provide needed motivation and focus for continued psychotherapy. Skill is required in treating these patients since there are rapid oscillations in distance-taking and mood, during which the patient frequently experiences abrupt and intense hostility. The hostility can be expressed in suicidal or homicidal states that call for careful management.

Finally, in certain cases, a relative of the patient can be profitably involved in treatment. When the patient is not too distrustful, the family member can be encouraged to resume or to form a symbiotic relationship under the guidance of the therapist. In this manner the father of one subject and the brother of another served as "back-up therapists." This prevented regression at times when contact with the therapist was interrupted by the patient. In these instances, subsequent resumption of therapy was largely due to the urging of the family member.

Opinions About Mental Illness and Political Ideology

BY ALEXANDER TOLOR, PH.D.

The author examines the relationship between attitudes toward mental illness and psychiatric patients on the one hand and reactions to the withdrawal of Senator Thomas Eagleton as a candidate for Vice-President on the other. A sample of 384 undergraduate college students was surveyed with the Opinions about Mental Illness (OMI) scale and a specifically devised political ideology scale. The results indicated that OMI factor scores were substantially related to political views.

THE 1972 PRESIDENTIAL ELECTION afforded those in the mental health field who are interested in evaluating public attitudes toward the emotionally disturbed a unique

An abbreviated version of this paper was presented at the 44th annual meeting of the Eastern Psychological Association, Washington, D.C., May 3–5, 1973.

Dr. Tolor is Research Professor of Psychology and Director, Institute for Human Development, Fairfield University, 611 North Benson Rd., Fairfield, Conn. 06430.

opportunity to investigate these attitudes in relation to political views. The withdrawal from the Democratic ticket of Senator Thomas Eagleton raised many questions about the appropriateness of the decision as well as the presumed negative attitude of the American voter toward the emotionally disturbed. In fact, the disclosure of Senator Eagleton's psychiatric history, including his experience with electroconvulsive therapy, captured the attention of the nation as very few mental health events had previously and prompted many people to focus on the possible impact of emotional problems on the future functioning of a nationally prominent figure. The "dumping" of Senator Eagleton produced a great variety of reactions, ranging from total agreement to complete disagreement with the decision. It may be presumed that individual differences in reactions were based at least in part on different views toward the emotionally disturbed.

I took advantage of these circumstances by conducting a survey to determine more precisely whether attitudes toward mental illness were related to people's views of the Eagleton decision. Moreover, the study attempted to ascertain whether specific aspects of people's attitudes toward mental illness distinguished between political orientations, voting preferences, and opinions on whether those with a history of emotional disturbance should hold high office.

METHOD

Subjects

The survey was conducted with 384 undergraduate college students ranging in age from 17 to 39 years, with a mean age of 18.7 years (standard deviation = 1.62). This sample therefore consisted primarily of a group of youthful voters, most of whom had only recently become eligible to participate in the national elections. In the sample, 61 percent were men and 39 percent were women; racially, 97 percent were white. In terms of class year, 59 percent were freshmen, 17 percent were sophomores, 14 percent were juniors, and nine percent were seniors.

Procedure

Each of the participating subjects was administered a questionnaire booklet containing a demographic data sheet, an eight-item political ideology scale, and the 51-item Opinions about Mental Illness scale (OMI) developed by Cohen and Struening (1). The political ideology scale dealt with reactions to the Eagleton affair, i.e., with whether the decision was regarded as being correct and whether Senator Eagleton's withdrawal adversely affected the respondent's outlook on politics in general or the party more specifically. One item asked whether someone with a history of previous emotional problems should be considered for high office; another item requested information on voting preference. Except for the last question, all items called for a "yes," "no," or "undecided" response. The items of the scale are presented in appendix 1.

The Opinions about Mental Illness scale (OMI) is based on the assumption that opinions about the psychiatrically disturbed are potentially multidimensional; these dimensions are considered to be identifiable through multiple-factor analysis. The OMI contains Likert-type items that have been demonstrated by Struening and Cohen (2) to have factorially stable scores on five dimensions of attitudes toward mental illness. Each of the component items is scored in the direction of its positive or negative factor loading.

The five salient OMI dimensions underlying opinions about serious emotional disturbance and mental patients are designated as authoritarianism, benevolence, mental hygiene ideology, social restrictiveness, and interpersonal etiology. Each of these has a specific conceptual meaning within a multidimensional context. For example, authoritarianism stresses the different and inferior status of mental patients; benevolence involves a kind, paternalistic view of patients, based on a religious or humanistic philosophy; mental hygiene ideology involves the endorsement of the views of mental health professionals; social restrictiveness embraces the notion that patients and former patients are socially dangerous; and interpersonal etiology considers mental illness to be grounded in interpersonal experiences, particularly deprivation of parental love during childhood.

Testing was done in small groups approximately four to five weeks before the November 7, 1972, election.

RESULTS

Overall Descriptive Data on Political Ideology Scale

Seventy percent of the respondents thought that the way in which Senator Eagleton had been treated by the Democratic Party after the disclosure of his psychiatric history was not essentially correct.

Although 83 percent thought Eagleton should have revealed his former emotional difficulties immediately upon being offered the Vice-Presidential nomination, 61 percent asserted that they had become more discouraged with the entire political process and 63 percent reported that their voting preferences had undergone a change because of the events surrounding Eagleton's nomination and subsequent forced withdrawal. Despite the disillusionment of a majority of respondents, only 13 percent indicated that their desire to cast a vote had diminished because of these circumstances.

A significantly ($\chi^2=4.97$, $p<.05$) higher proportion of students who identified themselves as Democrats than those who identified themselves as Republicans indicated a change in their voting preference because of the Eagleton affair (77 percent for Democrats versus 65 percent for Republicans). Moreover, there were significant differences ($\chi^2=7.23$, $p<.01$ and $\chi^2=15.75$, $p<.001$, respectively) between students who professed to be Democrats and those who professed to be Republicans as to whether dropping Eagleton was a proper course of action (45 percent of the Republicans and 28 percent of the Democrats agreed) and as to whether a previous emotional distur-

TABLE 1

Comparison of High and Low Scorers on the Five OMI Factors According to Differentiating Items of the Political Ideology Scale, in Percentages

Eagleton's forced withdrawal caused my discouragement with the political process.	63	33	4	58	29	13	8.76	p<.02

bance made someone seeking high office a poor risk (49 percent of the Republicans and 27 percent of the Democrats agreed).

Relation Between OMI Factors and Political Ideology

To determine whether differences in attitudes toward the mentally ill were related to responses to the political ideology questions, subjects were first divided into high scorers (above the median) and low scorers (below the median) on each of the five OMI factors. The results indicated that a substantial relationship between factor scores and political views did indeed exist. Of the 40 chi-square analyses, 17 yielded differences significant at the level of .05 or better.

As can be seen in table 1, those whose scores for authoritarianism were high differed significantly from those whose scores were low: they indicated less often that the Eagleton affair was handled incorrectly but more often expressed uncertainty about their reaction to its handling, less often reported discouragement with the political process, indicated less often that the Eagleton affair had diminished their desire to vote, less often changed their preference for a candidate, asserted more often that a person with a history of psychiatric illness is a poor risk, and were more often affiliated with the Republican Party (among high scorers, the preferences were Democratic=19 percent, Republican=50 percent, other or none=31 percent; among low scorers, the party preferences were 40 percent, 34 percent, and 26 percent, respectively; $\chi^2=20.98$, $p<.001$).

Respondents with high benevolence scores differed from those with low scores: they more often stated that the Eagleton situation was handled properly, less often reported disillusionment with the political process, and more often preferred the Republican position (among high scorers, the preferences were Democratic=26 percent, Republican=47 percent, other or none=27 percent; among low scorers, the party preferences were 33 percent, 35 percent, and 32 percent, respectively; $\chi^2=6.26$, $p<.05$).

Those with high mental hygiene ideology scores differed from those with low scores by being more often discouraged by the political process, having more often lost their desire to cast a vote, less often considering a psychiatric illness to make a candidate a poor risk for high office, and being Democrats relatively more often than Republicans (among high scorers, the preferences were Democratic=37 percent, Republican=43 percent, and other or none=20 percent; among low scorers, the party preferences were 22 percent, 40 percent, and 38 percent, respectively; $\chi^2=16.49$, $p<.001$).

Subjects with high social restrictiveness scores differed

from those with low scores: they felt relatively more often that the dumping of Eagleton was proper, more often regarded a person with a history of psychiatric illness as a poor risk for high office, and indicated relatively more often that they were Republicans (among high scorers, the preferences were Democratic=25 percent, Republican=43 percent, other or none=32 percent; among low scorers, the party preferences were 36 percent, 40 percent, and 24 percent, respectively; $\chi^2=6.55$, $p<.05$).

High scorers on interpersonal etiology differed from low scorers by showing less uncertainty in relating the Eagleton situation to a growing disillusionment with politics.

DISCUSSION

Although the group trends were not of sufficient magnitude, despite their statistical significance, to permit making individual predictions, the results indicated that attitudes toward the emotionally disturbed do show a general association with political beliefs. More specifically, the configuration of beliefs that includes stressing the different and inferior status of mental patients (i.e., a high score on authoritarianism), the rejection of the philosophy that is characteristic of mental health professionals (i.e., a low score on mental hygiene ideology), and the view that mental patients and former patients are dangerous to society (i.e., a high score on social restrictiveness) tended to be related to a Republican voting preference, a belief that a history of emotional disturbance should disqualify a candidate from serving in high office, a more favorable attitude toward the political process, and a greater desire to maintain the status quo. All of these results are consistent with the conceptual meaning assigned to the OMI factors.

The one surprising set of relationships was found in the benevolence factor. Those who took a kindly and paternalistic view of patients, on the basis of religious or humanistic ideologies, tended often to be Republican and also favored the Eagleton decision relatively more often than those who took a less kindly and paternalistic view of patients. It is possible that some of the people who had high benevolence scores perceived the dropping of Eagleton from the ticket as being in his best interest by sparing him extra responsibilities and undue stresses. In any case, it should be noted that the majority of both high and low scorers on the benevolence factor felt that the way in which the Vice-Presidential nominee had been handled was not correct.

The survey also suggested that in this group of young, recently enfranchised voters, McGovern's chances of winning the Presidency were seriously undermined by the Eagleton affair. In view of the general consistency between political and mental health views, it is apparent that a candidate who is known to have had major adjustment problems will evoke very different reactions in people of different political persuasions.

APPENDIX 1

Items of the Political Ideology Scale

For the first seven questions, the subjects were asked to respond "yes," "no," or "undecided." On the last question, they were asked to indicate their political preference.

1. The decision to drop Senator Eagleton as a Vice-Presidential candidate was a proper one.
2. The way in which Senator Eagleton was handled by those in control of the Democratic Party, after the disclosure of his psychiatric history, was essentially correct.
3. Senator Eagleton should have revealed to Senator McGovern his psychiatric history as soon as he had been offered the Vice-Presidential candidacy.
4. The forced withdrawal of Senator Eagleton from the Democratic ticket caused me to become discouraged (or more discouraged) with the political process.
5. My desire to cast a vote has diminished because of the fact that a candidate with previous emotional problems was asked to withdraw.
6. My position concerning the Presidential candidate I will vote for has not changed because of the events revolving around Senator Eagleton's nomination and subsequent withdrawal.
7. A person with a history of emotional problems is usually a poor risk for serving in high office.
8. At this time, my voting preference is: Democrat, Republican, undecided or none.

EDITORIAL

The Psychiatrist and Family Planning

INDIVIDUAL PSYCHIATRISTS, in concert with fellow mental health workers, colleagues in allied disciplines, and concerned citizens in the United States and abroad, are becoming increasingly aware of the complex societal and personal issues embedded in questions of human fertility and population. They are sensitive to the impact of unrestricted population growth upon our fragile biosphere and the quality of life it can sustain. At the same time they deeply feel their responsibility as clinicians concerned with the ethical, compassionate, and humane care of individuals and their families.

The American Psychiatric Association has been cautious in making an organizational approach to these questions. Its recent action, however, of appointing a Task Force on Psychiatric Involvement in Family Planning recognized the key roles played by some members of the psychiatric profession in assisting individuals and families to make the difficult choices about whether or not to practice contraception, terminate pregnancy, or preclude its occurrence on a permanent basis. It also opens the door to more systematic exploration of the problems confronting psychiatrists in the difficult borderland between individual and societal rights and responsibilities.

An initial need is to define and clarify some of the issues involved in this broad area. Family planning and formation are activities of individuals. Good family health is good mental health (1). Population planning, on the other hand, is a policy activity of governments and other societal institutions. This distinction has been implied by the World Health Organization: "Family planning is a way of thinking and living that is adopted voluntarily upon the basis of knowledge, attitudes and responsible decisions by individuals and couples . . ." (2). Informed, responsible decision making requires knowledge and readiness to accept or reject parenthood and family tasks. Yet the two kinds of activities, policy and personal, cannot always be clearly separated since individual decisions are made in a context of information, facilities, and constraints influenced by governmental and other institutional actions.

Major fertility-related decisions may be sexual, conceptive (proceptive or contraceptive), abortion-seeking, or procreative (3). They may lead to the use of specific procedures or techniques. Any new fertility-regulating method, like any biomedical advance, is effective only insofar as the utilizer—the individual human being—is able to make the necessary choices about its use in relation to others in his social environment. And a major component in this decision-making process is the quality of the interaction between service utilizers and service providers.

Family planning also has consequences that are not well defined. These include the social, psychological, and adaptive effects of particular decisions.

Psychiatrists have a responsibility to be professionally concerned with the psychosocial determinants and consequences of family planning. Their current involvement reflects a number of overlapping roles and capacities.

First, as members of a mental health profession, they depend on expertise derived from their training and experience in individual, family, and group dynamics and therapies. They may work with individuals who come seeking help or counsel or with insti-

In this section the Editor samples varied opinions on topical problems. The opinions expressed herein are not necessarily those of the Editor, nor can they in any way be construed as marking the official policy of the Journal.

tutions and agencies concerned with family planning, sex education, and other fertility-related matters.

Second, as medical specialists they are concerned with the psychosocial components of bodily change. They may be consulted, for example, about mental health aspects of infertility, sterilization, and abortions. They also carry responsibility for the mentally handicapped, including the hospitalized mentally ill and retarded. Family planning counseling and practice for these groups requires special attention to the legal and ethical aspects of fertility regulation in persons whose capacity for responsible decision making is uncertain. Moreover, as a physician the psychiatrist has access to social influence, which allows him (if he wishes) to be an agent of social change and to facilitate the acceptance of public health measures, including family planning programs.

Third, psychiatrists may function as behavioral scientists, often in association with colleagues from other disciplines. In this capacity a number are already involved in research on the psychological, social, and cultural determinants of fertility-choice behavior at different phases of the human sexual-reproductive career, on the acceptability of specific procedures, and on fertility regulation among the mentally handicapped.

Interdisciplinary and interprofessional collaboration are essential to family planning service, education, and research. Physicians, including psychiatrists, require information and guidance both to reduce indifference and to enhance the idea that family planning should become part of general health care. Since the bulk of family planning services (including personal counseling) in the United States and abroad will be carried out by indigenous workers, the education, training, and development of these workers must also be a major concern.

Man's imperfect but increasingly powerful ability to manipulate his own biological destiny and fertility present him with challenges and conflicts whose magnitude is only slowly being faced. Explicit attention to what many regard as an inviolable area of self-determination is often experienced as frightening (4). It is time for psychiatrists to heighten their sensitivity to evolving psychosocial concerns related to human fertility; in this way they may contribute to enhancing the quality of life for present as well as future generations.

BRIEF COMMUNICATIONS

What Is Psychiatry? A New Model of Service and Education

BY ALEXANDER Z. GUIORA, PH.D., AND SAUL I. HARRISON, M.D.

The authors review the history of mental health models as well as related systems of professional education and service delivery. The current situation is criticized as being too concerned with professional privilege and hierarchies while seeming to ignore both gaps in and duplication of services. The authors therefore suggest the need for more organizational paradigms for the mental health field; these are to be derived rationally from the community's needs and the expanding knowledge pool. To the authors this suggests a system of hierarchical education based on career steps that could be entered at various levels of competence and certification.

GEORGE ENGEL (1) recently posed a troubling question in the pages of this journal: Is psychiatry failing in its responsibilities to medicine? Although we would agree with most of the points made in his necessarily brief answer, we have found what he omitted to be disquieting. Obviously, editorials are not meant to be comprehensive; nevertheless, additional observations leading to broader recommendations seem vital for any serious assessment of the role of psychiatry today.

The issues we wish to stress here stem from a contemplation of the broad field of mental health as it has been affected by changing conceptual models and a growing imbalance between its systems of education and service delivery.

CHANGING CONCEPTUAL MODELS

The mental health professions have witnessed a cyclic ascent and decline of three conceptual models—biological, psychological, and social. We have seen mode after mode of intervention reach prominence and then be discarded because it fails to live up to its promises, only to rise and fall once again. We have known the arid years of hopelessness when there was only a rather primitive biological model. Following that we witnessed the spectacular rise of a psychological model—psychoanalysis—only to watch it decline in prestige. As the psychological model recedes, an upsurge of hope and activity is now centering on the biochemical field. In between came short-lived social models that never really blossomed except as an interlude between the two. We had the child guidance clinic movement in the 1920s, and the final judgment has not yet been made on the community mental health movement of the 1960s. Neither do we have sufficient distance yet to talk objectively about the resurgence in the 1960s of the behaviorism that was hailed in the 1920s.

Perhaps this sense of déjà vu has a vital lesson to teach us. The succession of conceptual models in the mental health field may mean that the essential human needs to which the field has contracted to minister have not yet been precisely identified. We currently conceive of such needs in terms of the familiar disease model. We try to minimize the vague discomfort we feel about its inadequacies by attaching qualifiers. Thus we speak at times of psychological illness, or organic illness, or social illness. What we neglect are those essential needs to which we as a field are not responding—the existential anxiety that attends upon human existence itself.

True, people get sick and specific remedies may exist. True, people get tangled up in psychic conflicts that psychotherapy may unravel. True, society impinges on the individual, and attention to the interfaces can give the individual relief. But these are not the whole story.

There are many who say that we mental health professionals have inherited a legacy that was never meant for us. Though we have never disclaimed the inheritance, we seem strangely unable to recognize its true nature, let alone to use it properly. We have in fact inherited the vacuum in which faith and belief, a priesthood and an all-inclusive value system—the Church—once held sway. Although we were unable to extend the same comforts in time of existential need, were unsure of our power of ab-

The advice of John Hartman, Ruth Marquis, and Jules Schrager is gratefully acknowledged.

solution and the certainty of salvation, and were clearly without a divinity or a divine dogma, we took on the mantle of priesthood. We have recast the existential needs into more familiar and less threatening medical terms. But alas, magic does not work on the nonbeliever. Renaming the central need has not changed it. We have only fortified an endless cycle of hope and despair.

Secondly, we need to consider how we in the mental health field organize the way we educate and certify. To continue with the priestly paradigm, we have become laden with esoteric knowledge and wisdom and privilege—all of which are of minimal use in the actual delivery of the service we have designed. One might say that we have formed a priesthood of learning and privilege, with elaborately separated orders. There are the orders of psychiatrists, psychologists, social workers, and other ministrants. Each order has its own set of hard-won privileges and is surrounded by hermetically sealed boundaries. Each order—in its quest for greater excellence, we presume—heaps layer upon layer of knowledge (or at least information) on the aspiring novice, who will ignore, it is hoped, all the overlap, duplication, and sheer waste.

By now, any effort to delineate the mental health professions forces our attention toward the overlapping, shared, and duplicated roles and functions among them. Indeed these common functions may exceed what is truly unique about the separate professions. For example, the increasingly minimal distinctions between some psychiatrists and some clinical psychologists suggest less than rational horizontal and vertical patterns of expertise or specialization. Examination reveals to how small an extent the supposed distinctions between the professions bear any sensible relation to community needs, to the shared knowledge pool, to a planned system for delivering service, or to our system of education.

THE BASIS OF DISTINCTIONS

Change has been rapid in the mental health professions and their scholarly disciplines. Education for the clinical psychologist has become more and more professionalized, and the education of physicians has been scholarized. Thus, "tradition" is no longer enough to explain the distinction between professions. By now it is politics, elitism, economics, and other self-serving internal dynamics of the professions that determine their boundaries.

Disturbing and radical as it may seem, should we not seriously consider the advantages and disadvantages of realigning professional designations in the mental health field? Should we not base professional distinctions on the realistic functions and roles that are needed instead of on factors unrelated to current and future needs? Shouldn't those needs be the ones to determine our service delivery system and how we educate people to prepare for it? And might this not lead us to reexamine and perhaps redefine the very meaning of the word "physician"?

To understand our present problem we need to ask where the elitism of physicians began. The concepts of professionalism proposed by Flexner (2) have had a lasting effect on medical education and very likely on other professions as well. Among the legacies to medicine that accompanied Flexner's goal of higher quality was a tendency toward elitist exclusionism. It is true that the pre-Flexner period was marked by less than adequate professional preparation—diploma mills, short courses, incomplete night schools, and other minimally adequate training procedures. Nevertheless it enabled many to practice medicine and resulted in an adequate supply of physicians, although too many had dubious qualifications.

Today medical education and most other professional education aims primarily, if not exclusively, at preparing only the highest level professional. The claim that it is for the protection of the public is a valid justification but there is the unfortunate by-product that too much of the public has no access to the high-quality professional—a circumstance which suggests that our present educational arrangement is not based on any rational correlation between recognized needs and available knowledge. Instead we follow the apparently unassailable dogma that the better the professional's education, the better the service he will render.

In theory this can hardly be challenged. But what evidence do we have that the intensive preparation pediatricians receive for diagnosis and treatment of the complex problems they encounter in pediatric training centers has improved either the quality or quantity of service they render for the respiratory infections, eating problems, and enuresis so commonly encountered in the community? This need for relevant training is even more important in the case of preventive work in the psychosocial areas of pediatrics.

To consider another area, is there any evidence that the increasing professionalization of nursing has improved the quality of nursing care delivered to the hospitalized patient? Although a doctorate in nursing may advance the profession's development, what effect does it actually have on the quality or quantity of nursing care delivered? Nursing developed to help the physician, whose techniques and areas of knowledge were expanding and growing more complex. The physician now requires the help of secondary professions such as nursing, social work, physical therapy, and inhalation therapy. Nursing, like all other professions, has created its own narrow vertical career ladder. But why can't the members of the secondary medical professions have access to a horizontal form of advancement on the career ladder? Why can't a nurse become a physician by building on what he or she has already accomplished? Why can't there be an interlocking system of permeable hierarchies?

The issue before us, then, is this: Should professional education be based on a series of vertical career steps in the hierarchy? The military has a medical support system founded on just such a hierarchy. The levels of expertise include the general duty corpsman, the specialized corpsman technician (e.g., operating room technician, psychiatric technician), and those capable of independent duty. People from these secondary ranks provide a major

source of the physicians' assistants in civilian life after they have completed their tours of duty. Perhaps this method of ordering medical care stems from the mission of military medicine, which is so unambiguously and narrowly defined that typically it does not need to concern itself with people's existential demands—only with the needs of the system.

In civilian life, by contrast, the mental health professions often promise far more than they can deliver. Worse, we seem to be promising a response to demands from the individual and society that are actually in conflict. Ultimately the individual wants relief from his existential anxiety, whereas society wants us to ensure that the individual is under social control.

THE NEED FOR A NEW PARADIGM

Many of these concerns have been expressed by others and have resulted in proposals to remedy the problems of both our own and other health fields. Comparable bold and broad-sweeping suggestions regarding the delivery of obstetrical services were articulated by Willson in his 1970 presidential address to the American College of Obstetricians and Gynecologists (3). Lawrence Kubie, considering the problem of overlap among mental health professions, has suggested that elements from the training programs of psychiatrists and psychologists be combined to form a new profession of psychotherapy (4–6). In 1971 the proceedings of a conference devoted to psychotherapy as an autonomous profession were published (7). More recently, Abroms and Greenfield (8) have suggested that we might resolve some of the problems of the current practice of psychotherapy if we were to teach and then license nonmedical psychotherapists to dispense drugs. Still others respond to the need for expanded services by recommending bringing into the delivery network the nonprofessional workers whose professional training may be less than that of other mental health workers, but whose expertise is forged by their own life experience.

All these approaches have merit, but none is conceived broadly enough to resolve the many facets of our dilemma. A bold design would call for revamping the whole system. Such a design would use elements of the Kubie model for the creation of a unitary profession. It would also incorporate the spirit behind the paraprofessional movement so that mental health careers could be entered at varying levels of competence and certification.

If one were to establish a system of hierarchical education based on such career steps, it might be wise to make it a complete system from top to bottom. The recent and sometimes violent confrontations between professionals and those in the newly established roles of indigenous paraprofessionals point up the need for this. Such an interlocking system of more accessible hierarchies should also begin training people at a younger age. It should have points of entry all the way to the top and should define the "lower" levels not only as more limited steps on the career ladder (which has a negative connotation) but also as more specialized ones (which has a more positive ring).

The current fashion of admiring the Chinese and Soviet systems causes us some constraint in citing them as examples. But in China the "barefoot doctor" has only a few months of formal training. The rural doctors are educated in a year, and they are followed in the hierarchy by the better educated "assistant doctors." In the Russian hierarchy there are the positions of feldsher, physician, specialist, and professor, each calling for additional education. In both cases the guiding principle is that of an interlocking system of permeable hierarchies of competence and certification.

More has been said here of our professional problems of education and delivery of service in mental health than of our other dilemma—the need for a more holistic definition of our existential needs. But perhaps improving the one situation would ameliorate the other. A more rational organization within the professions could one day be reflected in a more rational organization of care. Perhaps by expanding our delivery to include all the people we will one day be challenged to care for the whole human being.

Historical Background in Children with Affective Disorders

BY DONALD H. McKNEW, JR., M.D., AND LEON CYTRYN, M.D.

A study of the histories of 50 children with affective disorders revealed that certain environmental factors were present either singly or in combination in every case. When these environmental factors were related to the three types of childhood depression previously outlined by the authors, each category of depression could be linked with a characteristic cluster of environmental factors; for two of the categories, a specific environmental factor was present in every case studied.

THE EXISTENCE OF AFFECTIVE DISORDERS in childhood, although still a matter of dispute, is gaining increasing acceptance in the literature. One aspect of the matter that causes a great deal of controversy is the etiology of such disorders. People attack this issue from a variety of perspectives, including biochemistry (1), neurophysiology (2), endocrinology (3, 4), genetics (5, 6), and psychodynamics (7–14). Our own research group at the Children's Hospital of the District of Columbia has for the past four years been involved in a study of affective disorders in children from several of these perspectives. In a previous article in this journal we proposed a classification scheme for depression in childhood and briefly reviewed several aspects of childhood depression, including historical background (15).

To date we have seen more than 50 patients with affective disorders, 16 of whom were studied intensively in our research ward. Our examination of these patients' histories has revealed several modes of family interaction and certain types of specific events that occurred singly or in combination in all cases.

In this paper we will attempt to outline these recurring environmental factors and to delineate their relationship to the classification scheme for childhood depression proposed in our previous paper (15).

ENVIRONMENTAL FACTORS

Frequent Separations

A recurrent theme in many of our patients' lives has been frequent separations for periods of several months from important love objects, particularly during the first few years of their lives. For many of these children, it was a grandparent, baby-sitter, or some distant relative who functioned as the major love object in addition to a parent at some point in the child's maturing years. Frequently, episodes of reattachment to the original love object were followed by further separations. The child's substitute caretakers during the time of separation were frequently indifferent to the child or provided an unstable environment.

It is important to stress the fact that this was not the kind of deprivation in which there had never been an attachment to a significant love object or in which the significant object was withdrawn from the child's environment and no reattachment was ever allowed to occur, such as is often the case with chronically institutionalized children.

Sudden Loss

An experience common to many of our patients was the permanent loss of a crucial love object as a result of death, divorce, or a move away from the child's environment, with no further contact. The important factor here seems to be an excessive dependency on the particular loved one before the loss and the absence of any appropriate substitute after the loss. These children often functioned quite well until the loss of the love object.

Depreciation and Rejection

Many of the children we studied have suffered rejection and depreciation by their parents or loved ones either all during their lives or at least over a period of many years. Such rejection may take the form of blunt statements stressing the child's worthlessness or inadequacy, or it may be expressed more subtly through attitudes and actions that indicate a lack of respect, involvement, or caring. In some cases the parent has subjected the child to a constant barrage of criticism and humiliation. In other cases there is no frank rejection or depreciation, but rather a void in the parent-child relationship. The parents may or may not be consciously aware of their behavior.

In some instances this process of depreciation and rejection is related to some obvious characteristic of the child, such as a physical or mental handicap, or his sex, age, or position among his siblings. In other cases the process is much less obvious and requires a good deal of inference and extensive observation of the parent-child interaction to be understood.

Depreciation of the child can be shown through overprotection as well as through rejection; both attitudes convey the same basic message of the child's inadequacy

Both authors are Research Associates at Children's Hospital, 2125 13th St., N.W., Washington, D.C. 20009. In addition, Dr. McKnew is Assistant Clinical Professor and Dr. Cytryn is Clinical Professor of Child Health and Development and Psychiatry, George Washington University Medical School, Washington, D.C.

This work was supported by Public Health Service grant MH-40796 (Research Scientist Award to Dr. Cytryn) from the National Institute of Mental Health and grant RR-284 from the Division of Research Resources, National Institutes of Health.

and worthlessness. How much of the child's subsequent depressive outlook is caused by identification with this negative view of himself and how much is caused by a sense of alienation from important love objects is often hard to determine.

Loss of Involvement

In some situations a central figure in the child's life suddenly withdraws his interest in the child while maintaining a physically intimate presence. Here we are not discussing a noxious interaction with the child (as in the category of depreciation and rejection), but rather the loss of a crucial positive relationship in the absence of alternative love objects. Such a loss of interest on the part of the adult is usually related to such outside events as illness, personal tragedy, a change in involvement with other people (as in the case of remarriage), or a new baby in the home.

Depression in Parents

We found that in many of our cases at least one parent showed clinical evidence of depression. Some had been previously treated for depression. In some parents, however, the depression was manifested as a rather subtle mood disorder that never reached a clinical level requiring treatment.

Parental depression may affect the child either through the child's identification with the parent or through the parent's loss of involvement with the child as a result of his illness. Some children improved rapidly as soon as they were separated from their parents—a phenomenon we frequently observed when a child was hospitalized. This may be attributed to a lack of internalization of the parent's depression. In such cases the child's chronically depressed mood improved within one or two days and recurred only during parental visits. On the other hand, those children in whom the process of internalization seemed to be already operating remained depressed while they were away from their parents. This was true for children as young as six years of age.

DISCUSSION

We wish to stress the fact that we are merely describing historical events that we saw regularly occurring in the lives of our patients; we are not imputing to them any direct etiological significance. The presence of certain recurring environmental factors in our patients' backgrounds does not in any way preclude the existence of a genetic predisposition in some or all cases. Other limiting factors that should dictate caution in interpreting our findings are the relatively small sample, the retrospective method of eliciting historical material, and the lack of reliability of many of our patients' parents. When there is a dramatic, clearly circumscribed event, such as death or divorce, the relationship between such an event and the affective disorder is more easily established. However, many subtle parental behaviors (for example, scapegoating, withdrawal of affection, transient depressive affect) are irretrievable in retrospect as historical events, because of denial or repression of the behavior by the child or parent.

A finding that seems to favor the meaningful relationship between affective disorders and early childhood events is that each of the three types of childhood depression identified in our previous paper (15) can be linked to a characteristic cluster of environmental factors. These three categories of depression included acute depression, chronic depression, and masked depression.

Acute depressive reaction always followed a sudden loss or a loss of involvement. No instances of clinical depression in the parents were found within this category, although there were many instances of subtle mood disorders in the parents. Nor did we find any history of frequent separations from love objects or evidence of depreciation or rejection. On the other hand, every case of chronic depressive reaction was accompanied by clinically diagnosable depression in at least one parent. Within this category we also found many instances of frequent separations, some evidence of depreciation and rejection, and less frequent occurrences of loss of involvement. In the masked depressive reaction there was often an acute loss or a loss of involvement and almost always depreciation and rejection, but parental depression was found only infrequently.

In summary, our investigation suggests that the sine qua non in acute depressive reactions is the sudden loss of a love object and that the sine qua non in chronic depressive reactions is depression in at least one parent. In masked depressive reactions, however, there does not appear to be a universal factor.

Truth, Honesty, and the Therapeutic Process

BY LEON SALZMAN, M.D.

The place of honesty and truthfulness in the therapeutic process has rarely been discussed in the psychiatric literature, although Freud placed great emphasis on the need for truthfulness. The author affirms the importance of absolute honesty by both therapist and patient, but cautions that the patient's ability to be honest may be limited by neurotic defenses and that the therapist must use discretion in sharing his honest appraisals with the patient. "Truth" is distinguished from honesty by the author, and its place in therapy is evaluated.

A BASIC PREMISE of a therapeutic relationship and an essential part of the contract the patient makes in establishing it is to be honest and truthful. Although the concepts of honesty and truth are rarely mentioned in the psychiatric or psychoanalytic literature, Freud referred to them constantly. He stated:

> The psychoanalytic treatment is founded on truthfulness. A great part of its educative effect and its ethical value lies in this very fact. . . . Since we demand strict truthfulness from our patients, we jeopardize our whole authority if we let ourselves be caught by them in a departure from the truth (1).

In order for the therapeutic process to be useful to our patients, they must tell us what concerns them, with a minimum of distortion or withholding, to the extent that their emotional capacity and cognitive integrity permit. What is the therapist's part in this arrangement? How much should he tell or withhold from the patient? To communicate our feelings, attitudes, observations, or interpretations to our patients may be essential to the process of therapy, but at times such communication can be destructive. Is this countertransference or simply an essential part of the therapeutic arrangement?

Dr. Salzman is Deputy Director, Bronx State Hospital, 1500 Waters Pl., Bronx, N.Y. 10461, and Clinical Professor of Psychiatry, Albert Einstein College of Medicine, New York, N.Y.

THE DISTINCTION BETWEEN HONESTY AND TRUTH

First, we must clarify our concepts. Honesty is not the same as truth, although the two are related. Webster defines truth as "the state of being the case: fact," while honesty is defined as "fairness and straightforwardness of conduct or adherence to the facts." I would like to suggest that honesty is a dynamic concept that is based on an individual's sincere and objective attempt to appraise a total situation and that is limited by his inability to be totally unbiased. Truth, on the other hand, is a matter of definition and varies according to the framework in which it is established—whether scientifically, as in natural laws, or morally, as determined by man or God. As Oppenheimer has stated, "Truth is so largely defined by how you find it" (2, p. 101). He meant simply that what is true depends upon how one sets out to determine the truth.

This distinction is crucial in a discussion of the place of truth, honesty, and trust in the therapeutic process. For example, we must recognize that honesty is not exclusively a moral issue, since it is determined by the degree of freedom the person has to explore, express, and determine the truths in his environment. A person's honesty is strongly influenced by the amount of neurotic defenses he has and the degree of distortion he unconsciously imposes on the environment by such behaviors as denial, projection, or dissociation. The degree of honesty a person expresses is determined by the amount of security and self-esteem he has, which allows him to be more or less honest in seeing a situation as it really is. Dishonesty, whether consciously elaborated or unconsciously demonstrated, is a defensive maneuver designed to support a neurotic system. We distinguish between the deliberate and the unconscious liar only because we still tend to assign moral judgments to those types of distortion.

Is the child lying when he tells you about the fire engine drawn by elephants and led by a maharajah, à la Dr. Suess, or is he simply using his imagination? Are our patients being dishonest when they deny that they are ir-

ritated when we cut short their hours—because they are afraid we will get angry and terminate therapy? Is a patient being dishonest when he unconsciously falsifies a childhood experience by remembering it as having been bitten by a dog rather than as having kicked and hurt the dog?

These examples illustrate some of the vagaries of the concept of honesty and demonstrate why it cannot simply be appraised but must be understood in the context of the experience. Honesty is the potential to see a situation for what it is; it is achieved only when one has a minimal need to defend oneself against anxiety because one has sufficient self-regard. Whether we communicate this honest appraisal of a situation in a truthful statement or withhold it for reasons we believe are justified, our goal in the training of therapists should certainly be to encourage and develop basic honesty in our human contacts. Dishonesty is the inevitable consequence of the neurotic structure and occurs when a person's defenses demand some distortion of reality—by total reversal, slight distortion, exaggeration, minimizing, shading, etc. In therapy, this tendency is generally not categorized as dishonesty but rather is considered a problem of defense. The therapist should refrain from moralizing judgments and recognize that these distortions are a necessary activity in the neurotic state.

This link between neurosis and dishonesty has led many theorists, particularly Horney and Sullivan, to consider neuroses immoral and to classify them as "ethical diseases." Certainly the neurotic is dishonest but, since he is unable to make any choices, his dishonesty is imposed upon him by his neurosis. He does not wish it and would like to rid himself of it. The psychotic individual, whether his psychosis is of an organic or psychological origin, likewise describes events and experiences in a manner that deviates widely from fact. These reports are labeled delusions, hallucinations, faulty perceptions, confabulations, and the like. The issue of honesty or truth is not raised in regard to them, although we occasionally designate malingering as a deliberate attempt to deceive or defraud. In therapy we prefer to talk about defenses rather than honesty, since the problem of honesty is very loaded with ethical and theological judgments.

The matter of honesty leads us to an examination of the concept of truth. There are many interesting definitions of truth. All of them are true, yet none of them is entirely true. And this is precisely the limitation of the concept of truth, unless we believe in an absolute truth. To say that something is absolutely true is immediately to tell a lie, for truth is entirely dependent on our frame of reference, as Einstein plainly demonstrated in his experiments in relativity. Yet if we limit our definition of truth to some relativistic or indeterminate sense, we have chaos. Consequently, civilized societies have agreed on some basic truths as a foundation for morality.

HONESTY AND TRUTH IN THERAPY

In the therapeutic process honesty is an essential for patient and therapist. It is unthinkable that a rational, humanistic, nonauthoritarian healing process can take place without it. Yet it is too often demanded of the patient and not often enough required of the therapist. Many therapies, such as magic, proceed in an atmosphere that could be described as dishonest, but these are not subsumed under the strict category of psychotherapy by mutual exchange, as defined by Freud.

What needs to be clarified is not whether one should be honest, but how to use our hónest evaluations in an effective way. This is exclusively a question of technique, or at least it should be. Although we should not knowingly deviate from honest appraisals in our therapeutic work, we must constantly decide how best to utilize these appraisals. The question is not when should we be honest but when should we communicate our honest observations so that they most effectively serve the therapeutic process. In the case of a patient with incipient schizophrenia, there is no question about *whether* we should interpret to him a dream caused by severe anxiety that presages emotional disorganization; it is only a matter of *when* to do it. Likewise, we must decide *when* to inform a patient that we dislike some behavior and find it obnoxious (not should we or should we not).

The therapist's honesty in appraising such situations must be assumed and required without question. *What* we communicate, however, is a different question from whether or not we honestly appraise the total situation. We must not confuse honesty with technique, for without a basic honesty the therapy itself is in jeopardy and the technical problem never arises.

Unfortunately, for many therapists this decision never occurs, for they automatically decide to withhold unpleasant or distressful observations from patients because of their own inability to handle the consequences. In such cases, however, we are not dealing with honesty or truth but with an incompetent or immature therapist who has greater concern for his own welfare than for that of his patient. At times, of course, it may be the overwhelming characterological problems of the patient that put the therapist on the defensive, and one must acknowledge that this can happen to any therapist, however skillful, experienced, or mature.

On the matter of truth I think we can be much clearer. I cannot visualize many situations in which an untruth can be justified in the healing profession. Certainly we can argue endlessly about the dilemma of the patient with incurable cancer, but, aside from this, I think we would all agree that in the psychotherapeutic process an untruth is never justified. This must be clearly distinguished from withholding the truth for definable reasons. Our rationalizations may be incorrect, our justifications fallacious, but withholding the truth is quite different from telling a patient a lie. Freud made this clear in his statement quoted above. Certainly it is easy to justify withholding the truth from patients for reasons ostensibly beneficial to them when we are really protecting ourselves. It is easy to blame failures in therapy on our patients when our own skills are at fault. But this is a matter of recognizing our own deficiencies. In my opinion our patients

are better able to handle unpleasant material than we ever give them credit for.

Yet here again we must not confuse technique with truth. In the present state of development of psychological theory our interpretations and observations are a long way from being verifiable, and consequently we may not be withholding a *truth* if we refrain from making an interpretation, but only an *opinion*. We can establish some honesty in our appraisal only if we allow ourselves the freedom to examine human experience from a standpoint that is not biased or preconceived. The truthfulness of these observations will be determined somewhere far in the future.

At present we work only with skilled guesses, approximations, and rudimentary scientific observations and we must never fool ourselves about this fact. Frequently we present our educated guesses and approximations to our patients as though they were established truths. Such misrepresentations are as harmful as lying or withholding, and perhaps more so, since they occur so frequently. We must avoid the temptation to use our status to establish a set of "truths" that may be far removed from any acceptable definition of truth.

The purpose of distinguishing between honesty and truth in therapy is to stress the wisdom of using certain technical interventions in the therapeutic process. Although there is no virtue in a doctrine of absolute truthfulness in the therapeutic process, there seems never to be a justification for deception. But just as honesty is relative to the patient's sense of security, so must we recognize that the therapist is also human, and therefore subject to neurotic difficulties, defending himself with denials, and seeing less than the whole truth. We hope, however, that he has less need for such defenses than the patient does, and consequently we believe we have a right to expect less deception on his part.

Once More: The Inaccuracy of Non-EEG Estimations of Sleep

BY BRIAN L. WEISS, M.D., RICHARD J. MCPARTLAND, M.E.E., AND DAVID J. KUPFER, M.D.

To test the validity of nurses' estimates and patients' self-reports of the duration and quality of the patients' sleep, the authors compared these estimates with measures of sleep taken with the electroencephalogram. The authors found that nurses correctly estimated the amount of sleep of only two of the 14 subjects and tended to consistently overestimate. Patients showed no tendency to consistently overestimate or underestimate, but only four of the 14 patients correctly estimated the duration of their sleep. The authors argue that conclusions about sleep patterns that are based on observational methods will have to be reexamined.

SINCE CHANGES in sleep patterns have been observed in the course of many psychiatric disorders, it is now widely held that understanding the nature and extent of these changes will assist in the diagnosis and treatment of mental disorders. All-night electroencephalogram (EEG) sleep studies have already yielded significant information about the sleep patterns of acute schizophrenics, psychotic and nonpsychotic depressives, and psychotic alcoholics (1–5). Although the validity of the EEG in distinguishing sleep from waking states is beyond dispute, EEG sleep equipment is expensive and not widely available, and this prevents its broad use in clinical settings. Instead, observations and estimates by nurses and family members and self-reports by patients have been employed routinely; until recently, many conclusions about sleep patterns in psychiatric disorders have been based primarily on these observational methods (6–10).

At the time this work was done, the authors were with the Department of Psychiatry, Yale University School of Medicine, and the Connecticut Mental Health Center, New Haven, Conn. They are now with the Department of Psychiatry, University of Pittsburgh School of Medicine, Western Psychiatric Institute and Clinic, 3811 O'Hara St., Pittsburgh, Pa. 15261, where Dr. Weiss is Assistant Professor, Mr. McPartland is Research Associate, and Dr. Kupfer is Associate Professor and Director of Research.

This work was supported in part by Public Health Service grant MH-70012 (Research Scientist Development Award to Dr. Kupfer) from the National Institute of Mental Health.

The authors wish to thank the staff of the Research Unit, Connecticut Mental Health Center.

Although one earlier study reported a high degree of agreement between nurses' estimates of sleep duration and measurements taken by the EEG for psychiatric patients with unspecified diagnoses (11), a more extensive study found serious discrepancies between EEG measurements and the systematic observations by nurses of the duration of sleep in depressed patients (12). However, a high positive correlation between EEG measurements and nurses' estimates was noted in the case of patients with acute schizophrenia. The patients' own estimates of their sleep duration were not included in this report, and therefore no comparison with the nurses' estimates or the EEG measurements was obtained.

Since EEG measurements, nurses' estimates of sleep duration, and patients' self-reports on the quality and duration of their sleep were routinely recorded in our clinical research setting, we were able to compare the validity of subjective techniques with the EEG measurements as well as determine whether the patients' reports of sleep quality are correlated with any of the measures of sleep duration.

METHOD

Fourteen hospitalized patients (seven with depressive syndromes and seven with schizophrenia) were studied on the psychiatric research ward of the Connecticut Mental Health Center. Using standardized clinical interviews, the Brief Psychiatric Rating Scale (13), and patient self-rating forms (14), three psychiatrists independently diagnosed each patient. Our studies were not begun until at least two weeks after the patient's admission. The characteristics of the 14 patients are shown in table 1. All-night EEG measurements, nurses' observations, and patients' self-ratings of the duration and quality of sleep were recorded for each of the 14 patients for 14 consecutive nights; 196 seperate records were therefore made.

Continuous EEG, submental electromyogram, and horizontal electrooculogram recordings were made while the patients slept in their own beds on the research ward. These records were evaluated according to standardized techniques (15) by a scorer who was unaware of the patients' or nurses' ratings. At 30-minute intervals, using averted flashlights, nurses who had been trained on the research ward routinely and conscientiously observed whether each patient was asleep or awake. The patients were instructed to raise their hands as the nurses entered their rooms if they were awake. A patient was considered to be asleep if he displayed regular respiration, closed eyes, relaxation and immobility, and relative lack of response to minor environmental stimuli. The nurses then immediately recorded each observation.

All patients were routinely asked after each night of their hospitalization how many hours (to the nearest half hour) they had slept. The question was posed seriously, and only serious replies were tolerated. In addition, each patient was asked to rate the quality of his sleep that night on a scale of 1 to 5 (1 = very poor, 2 = poor, 3 = fair, 4 = good, 5 = very good).

TABLE 1

Diagnosis	Number	Age Range	Mean Age	Sex	
				Men	Women
Depression	7	25–63	49.7	1	6
Schizophrenia	7	17–27	21.6	4	3

The data that were obtained from the EEG measures, the nurses' estimates of sleep duration, and the patients' estimates of sleep duration and quality were analyzed by use of the Pearson product-moment correlation coefficient and the t test for paired observations. The nurses' and patients' estimates were considered valid if: 1) their correlation with the EEG measures was significant at the .05 level of confidence or better and 2) the two-tailed t test showed no significant differences (i.e., $p > .05$) between the estimates and the EEG measures; these criteria for validity have been used previously (12). The requirement that p be greater than .05 on the t test was designed to eliminate high correlations that are the result of patients' or nurses' consistent overestimation or underestimation of the duration of the patients' sleep.

RESULTS

Our results demonstrated a marked lack of validity in both nurses' and patients' estimates of sleep duration (tables 2 and 3). The nurses were able to make valid estimates for only one depressive and one schizophrenic patient. The patients' self-estimations were only slightly more accurate. Of the 14 patients, one depressive and three schizophrenic patients were able to satisfactorily estimate the number of hours they had slept. The depressive group slept an average of 342 minutes and the schizophrenic group averaged 393 minutes.

In the overall sample, nurses' and patients' estimates did not correlate highly with each other. In each of the two patient groups, only three out of seven patients' estimates reached acceptable levels of correlation with the nurses' estimates.

The data were further analyzed to determine whether any consistent overestimation or underestimation was made by the nurses or patients. It was found that the nurses overestimated the sleep of all seven schizophrenic patients (the average overestimation was 63 minutes per night, $p < .01$) and the sleep of four of the depressed patients. Neither schizophrenic nor depressed patients showed any consistent tendency toward overestimation or underestimation.

Correlations between the patients' ratings of the quality of their sleep and the EEG measures, nurses' estimates, and patients' estimates of the duration of their sleep are shown in table 4. The patients' ratings of sleep quality were correlated significantly with the EEG measures for only two depressed and three schizophrenic

patients, with the nurses' estimates for two depressed and three schizophrenic patients, and with the patients' estimates of duration for three depressed and three schizophrenic patients. Only four of the 14 patients' ratings of sleep quality showed significant correlations with all three measures of sleep duration. For more than half the patients, there was no statistically significant correlation between the total amount of sleep as registered on the EEG and the patients' subjective impressions of the quality of their sleep.

DISCUSSION

Our results cast serious doubts once again on the validity of either nurses' or patients' estimations of sleep and on their usefulness in clinical research. Nurses were particularly erroneous, since they accurately gauged the sleep of only two of the 14 patients. The fact that systematic observations of sleep by nurses are not valid for depressed patients has been noted before (12); our replication of this finding is especially noteworthy, because sleep disturbances in depressive syndromes have received widespread attention. Some diagnostic subgroups of depressive illness have been established on the basis of sleep patterns (8, 16–18) and changes in sleep patterns have been used in part to determine the effectiveness of certain treatment methods (19–23). However, conclusions like these, based on the findings of studies that rely solely on nurses' or patients' observations of sleep patterns, may have to be discarded.

With regard to acute schizophrenia, our findings do not support those of a previous study in which nurses' estimates of the sleep of schizophrenics were found to be valid (12). This discrepancy may be attributable to differences in the severity of illness of the patients. The seven

acutely schizophrenic patients in the previous study were highly agitated and they were in the most intense phase of their illness. Since these patients tended to be quite active when they were not asleep, there was usually a clear distinction between their waking and sleeping states. By contrast, the seven schizophrenics in our study, although they were all actively psychotic, usually remained in their beds at night. This difference is reflected in the fact that the schizophrenics in the earlier study slept an average of only 312 minutes each night, compared with 393 minutes in our study. It is not surprising therefore that the nurses' estimates of sleep for our schizophrenic patients were just as invalid as those for the depressed group. In addition, the nurses' ratings were characterized by consistent overestimation for all seven schizophrenics.

Furthermore, the patients' estimations of their sleep duration were also invalid: only one depressed patient and three of the seven schizophrenics could accurately assess their total sleep time. The not uncommon clinical situation in which the nurse and the patient disagree over how many hours of sleep the patient has had that night is easily understood in the light of these findings. No significant trends toward overestimation or underestimation could be discerned in the patients' self-ratings.

The lack of correlation between the patients' ratings of the quality of sleep and the various measures of sleep duration suggests that factors other than the amount of sleep a patient gets are involved in the subjective assessment of sleep quality. These factors may include the amount of time spent in the various sleep stages, such as stage 4 or stage REM; incidents of sleep disruption, such as intermittent nocturnal awakening; or changes in other characteristics of sleep, such as sleep latency. When "poor" sleepers were compared with "good" sleepers, a higher level of physiological functioning, especially an increase in body movements, was reported (24, 25). High positive correlations between the number of body movements during sleep and levels of nighttime telemetric activity have also been reported (26) and nighttime activity levels have also been significantly correlated with other measures of sleep disruption, such as reduction in the total time spent sleeping and an increase in sleep latency, intermittent awakening, and early morning awakening (5, 26, 27). It may be that sleep quality is inversely related to the level of psychomotor activity. Therefore, hypnotic drugs that merely increase the duration of sleep without affecting levels of psychomotor activity may not be effective in improving the quality of sleep. We are currently investigating these possibilities in our attempts to use objective indices of sleep in our research.

Imipramine Withdrawal: An Akathisia-Like Syndrome

BY GREGORY L. SATHANANTHAN, M.D., D.P.M., AND SAMUEL GERSHON, M.D., D.P.M.

The authors report on three patients who developed an akathisia-like syndrome after the abrupt withdrawal of imipramine. They discuss a possible link between this phenomenon and dopamine turnover in the central nervous system.

WITHDRAWAL SYMPTOMS after cessation of neuroleptic drugs have been reported in the literature (1, 2), but none of the reports has linked the withdrawal symptoms to any biochemical phenomenon. This paper describes three patients who developed withdrawal symptoms after abrupt discontinuance of imipramine. A possible biochemical basis for this phenomenon is offered.

CASE REPORTS

Case 1. This patient, a 42-year-old white man, was admitted to Bellevue Psychiatric Hospital with a diagnosis of psychotic depression. On examination he was found to be severely depressed, had clear-cut suicidal ideation, and felt hopeless, helpless, and worthless. Motor retardation, insomnia, and loss of weight were also associated with his illness. He had had two previous episodes of such symptoms; this episode had begun two weeks earlier. He was started on 75 mg. of imipramine (Tofranil) a day in three divided doses; this was increased to 450 mg. daily, also in three divided doses. At the end of three weeks on the medication the patient's condition had not improved. In fact, his clinical status showed a mild deterioration. At this time the imipramine was discontinued, and no other medication was substituted. About 24 hours after discontinuance of the imipramine he developed acute anxiety and restlessness. He could not stay still but paced up and down the ward. His behavior was observed for about two hours, then he was given 75 mg. of imipramine by mouth. His symptoms abated within an hour and a half. The dosage was decreased from 75 mg. three times a day to zero over three days without a recurrence of the symptoms.

Case 2. This 55-year-old white man was admitted to Bellevue with a diagnosis of manic-depressive illness, depressive phase. He had been ill for about two weeks. At the time of admission, he was found to be severely depressed, with feelings of hopelessness and worthlessness. The reason for the admission was a suicide attempt—he had tried to cut his wrists. He was placed on imipramine in increasingly larger doses; at the end of the three weeks, he was receiving 375 mg. a day in three divided doses. In spite of this treatment he showed a steady deterioration. At this point the imipramine was discontinued, and he was given no other medication. About 24 hours later he developed acute anxiety and motor restlessness; he too paced up and down the ward. Within two hours after the oral administration of 100 mg. of imipramine the symptoms disappeared. The imipramine was gradually discontinued over a period of three days, with no recurrence of the symptoms.

Case 3. A 40-year-old black woman was admitted to Bellevue with a history of psychotic depression. This was her first psychiatric admission. She was depressed and expressed feelings of hopelessness and worthlessness and also exhibited motor retardation, insomnia, and loss of weight. She was placed on increasing doses of imipramine until she reached a maximum dose of 300 mg. a day, given in three divided doses. Her symptoms cleared after about two weeks. At the end of four weeks in the hospital she was discharged with instructions to take 300 mg. of imipramine a day in three divided doses, but she failed to have her prescription filled. She came back to the ward the next day (about 24 hours after her last dose of imipramine) in a state of acute anxiety and motor restlessness. A dose of 100 mg. of imipramine was given orally, and her symptoms subsided within two hours. Once home, she continued to take her imipramine and the symptoms did not recur.

DISCUSSION

Withdrawal reactions to imipramine have been reported a number of times. Kramer and associates (3) studied 45 patients and reported that 25 of them developed withdrawal reactions, which consisted of nausea, headache, dizziness, and muscular pain. Mann and MacPherson (4) described two cases of nausea, vomiting, dizziness, and anxiety after cessation of imipramine. Anderson and Kristiansen (5) reported similar withdrawal symptoms in 15 of their 85 cases.

The three patients reported by us developed acute anxiety, motor restlessness, and inability to sit still. The clinical picture was indistinguishable from akathisia—a state that might be caused by depletion of or hypersensitivity to dopamine in the central nervous system (6). The fact that this akathisia-like syndrome appeared after imipramine had been abruptly withdrawn and disappeared when the imipramine was again started establishes that this syndrome is specifically related to the withdrawal of the drug. Further, this type of reaction appears in both responders and nonresponders to imipramine; of the three patients reported here, two were nonresponders and one was a responder.

Drs. Sathananthan and Gershon are with the Neuropsychopharmacology Research Unit, Department of Psychiatry, New York University Medical Center, 550 First Ave., New York, N.Y. 10016, where Dr. Sathananthan is Clinical Instructor of Psychiatry and Dr. Gershon is Professor of Psychiatry.

The authors thank Dr. E. Friedman for his advice during the preparation of this paper.

Since akathisia and certain hyperactive states are related to central dopamine mechanisms, we considered the possibility that this withdrawal phenomenon might also be mediated through a similar mechanism. Schildkraut (7) postulated that the clinical action of imipramine is due to its ability to prevent the reuptake of norepinephrine into the neurons, thus making more norepinephrine available at the receptor site. Carlsson and associates (8) postulated that the action of imipramine is similar to, but mediated through, serotonin. Whether dopamine is implicated in the action of imipramine is unclear; evidence in the literature is sparse. Glowinsky and associates (9) reported that, in rat brain, desmethylimipramine—a metabolite of imipramine—caused a slight increase in the H^3-dopamine levels. Friedman and Gershon (10) stated that tricyclic antidepressants do not inhibit the uptake of dopamine into aminergic neurons in the brain. In both these reports, imipramine was given in an acute loading dose. Data on chronic administration of imipramine leave the question of depletion of dopamine in the central nervous system unanswered (11).

There is evidence that drugs with known antidopamine activity alter hyperkinetic symptoms (12). In view of this, we postulate that the akathisia-like syndrome seen in our three patients might have been due to sudden functional depletion of dopamine at the receptor site. Over the three-week period of imipramine treatment in these patients, there was an accumulation of dopamine in the receptor site, by mechanisms similar to those postulated for norepinephrine and serotonin. The abrupt withdrawal of imipramine caused a sudden decrease in dopamine at the receptor site. This, together with the fact that imipramine does not significantly increase the synthesis of dopamine in the brain, caused a functional decrease in the available dopamine in the central nervous system. This functional depletion of dopamine or the hypersensitivity of the neurons to newly synthesized dopamine might have caused the akathisia-like syndrome. This hypothesis fits in with the probable explanation for the occurrence of this syndrome in parkinsonian patients (13).

Another explanation of the withdrawal symptoms was offered by Shatan (14). He suggested that the symptoms are due to the fact that imipramine may have the properties of a potentially addictive drug—that it causes a withdrawal phenomenon—and that this withdrawal can be corrected by the reintroduction of the drug. Whatever the explanation, this syndrome appears to have a biochemical basis since it occurs in both responders and nonresponders to the drug, in both unipolar and bipolar depressives, and in both sexes, and the symptoms disappear when the drug is reinstituted.

Incompetency To Stand Trial: Is Psychiatry Necessary?

BY RICHARD H. BENDT, M.D., EUGENE J. BALCANOFF, M.D., AND GREGORY S. TRAGELLIS, M.S., J.D.

Although psychiatrists disagree about whether they should have a role in the courtroom, the legal system continues to ask their help in evaluating defendants' competency to stand trial. The authors present four case reports that illustrate how psychiatrists can and should participate in the legal process. They also suggest that psychiatrists may be able to help protect a defendant's right to a speedy trial by preventing unnecessary hospitalization.

THE NEED for collaboration between the courts and psychiatrists is made apparent by the continued practice of hospitalizing defendants for the purpose of determining their competency to stand trial, especially when these hospitalizations take place under a criminal commitment. It has been demonstrated that criminal commitment is antitherapeutic in comparison with civil commitment (1). The degree to which the problem still exists is reflected by statistics from the Division of Legal Medicine for the Commonwealth of Massachusetts. From July 1, 1971, to June 30, 1972, there were 1,888 observational commitments to state hospitals in Massachusetts for determinations of competency; 501 of these took place at the maximum security facility at Bridgewater State Hospital. Only 76 of the total 1,888 were actually determined to be incompetent.

Despite the fact that psychiatrists are increasingly called upon to perform pretrial examinations of alleged offenders, there is marked disagreement among psychiatrists about their role in such examinations. In *The Crime of Punishment* (2), Karl Menninger maintained that the psychiatrist should be "excluded from the courtroom" because he is called upon to answer "highly technical questions." John M. Suarez, who has done extensive work in the field of legal psychiatry, has stated that the psychiatrist should have no role in handling an alleged offender until he has been found guilty (3, 4). Suarez' major feeling is that psychiatrists should attempt to change legislation, not involve themselves in pretrial issues. In *Psychiatric Justice*, Szasz asserted that the psychiatrist functions as an agent of the state in trial matters (5). On the other hand, in *The Role of Psychiatry in Law*, Manfred Guttmacher wrote that the psychiatrist should give clinical information relevant to a defendant's capacity to respond to the legal process (6). It was his opinion that the ultimate decision regarding the defendant's competency to stand trial is judicial and that the jury must make the final determination of criminal responsibility. In our court clinic practice, we support his point of view.

We work in the Psychiatric Court Clinic, which is part of the Criminal Division of the Suffolk Superior Court. The two psychiatrists assigned to this clinic (R.H.B. and E.J.B.) have had considerable training and experience in forensic psychiatry. We have also served on a five-year interdisciplinary research project engaged in the examination of the issue of competency to stand trial in Massachusetts.[1] The third member of the staff (G.S.T.) is a lawyer and a psychiatric social worker, a combination that provides a unique advantage in evaluating the defendants and using psychiatric information in the legal process. He is especially helpful in preventing prejudicial errors, particularly in pretrial issues.

This court clinic, established in 1954, is one of 24 such clinics throughout Massachusetts, but it is the only one that functions specifically at the superior court level. Although it has a role in the treatment of offenders, its special function is that of amicus curiae (7), assisting the court both before and during the trial in cases that involve serious and complex psychiatric issues. To facilitate our work, we developed a protocol for the psychiatric referral of alleged offenders by the courts (8). Since the protocol has been in use as a routine referral procedure, it has clarified the issues raised by the court and thereby improved communication among all the people involved in the court's activity. It has also assisted in protecting the defendant from unnecessary hospitalizations.

When the question of a defendant's competency to stand trial is raised by the judge, district attorney, or defense attorney, and if a psychiatrist is not available, the defendant is committed to a state hospital for a period of observation (under Chapter 123 of the general laws of Massachusetts, the period of observation would last at least 20 days). When all studies are completed, the court is notified to transfer the defendant back to the county jail. The defendant must then wait there until his case can be scheduled for a hearing on the issue of his competency. If he is found competent, a trial date will then be set. Because of these transfers and delays in scheduling, the de-

The authors are with the Suffolk Superior Court Clinic, Boston, Mass., where Dr. Bendt is Staff Psychiatrist, Dr. Balcanoff is Director, and Mr. Tragellis is Psychiatric Social Worker. In addition, Dr. Bendt is Instructor in Psychiatry, Harvard Medical School, and Assistant Psychiatrist, McLean Hospital, Belmont, Mass. 02178; and Dr. Balcanoff is Instructor of Clinical Psychiatry, Harvard Medical School, and Lecturer in Psychiatry, Boston College School of Law.

[1]The project, "Competency To Stand Trial and Mental Illness," was supported by Public Health Service grant MH-18112 from the Center for Studies of Crime and Delinquency, National Institute of Mental Health.

fendant may languish in jail for a period of one to three months, and sometimes even longer. An additional problem is that as the defendant is transferred from the hospital to the jail, whatever treatment may have been prescribed for him is often terminated abruptly. Consequently, the defendant may become incompetent once again, a development that will further delay his coming to trial.

CASE REPORTS

Case 1. P.F., a 20-year-old, unmarried man, was brought before the court on a charge of assault and battery with a dangerous weapon. At his first court appearance, he was overtly disorganized and behaved inappropriately. The judge raised the possibility of hospitalization and requested consultation with the court psychiatrist. When the defendant was interviewed about the alleged crime, he told the psychiatrist that an X ray of his skull would reveal "a lot of debris" in his head. He felt that the wax in his ear was part of this debris and that his teeth were also somehow influenced. Although he was oriented as to time, place, and person, his preoccupation with his delusions prevented him from focusing on the reason for his being before the court. Medication was prescribed: 100 mg. of thioridazine (Mellaril) twice a day and 2 mg. a day of trihexyphenidyl (Artane). Within a week he was reexamined and, although some psychotic delusional material was elicited during his mental status examination, his reality was sufficiently restored that he could describe the events surrounding the alleged offense. Medication and supportive therapy during the time he was in custody were essential to his becoming competent to stand trial. He was thus enabled to assist his attorney in preparing his defense. The further delay that would have resulted had he been hospitalized was thereby avoided.

Case 2. F.C., a 22-year-old black man, was brought to court on several charges of rape and assault with intent to rape. During his initial competency hearing, he became extremely anxious and suspicious. He viewed the judge as "grouchy" and felt that he was unable to have a fair trial. His attorney believed that the defendant could not adequately work with him in developing a defense and moved that he be readmitted to the hospital at which he had been observed. In the course of the hearing, his suspiciousness increased and he physically assaulted six court officers. He was seen both immediately and during the following day for a total of two hours of supportive psychotherapy. The psychiatrist tried to explain to the defendant his situation and helped him identify the anxieties and distortions that had limited his ability to cope in the courtroom. Following these interviews, he became less disturbed and was able to work with his attorney to reach the decision that it was in his best interest to enter a plea of guilty in the face of overwhelming evidence. This psychiatric intervention prevented hospitalization.

Case 3. M.C., a 24-year-old white man, was brought before the court on charges of breaking and entering. Because of his arrest, he had to stop his use of oral and intravenous barbiturates abruptly. When he appeared in court the next day for his arraignment, he had an outburst of violent behavior, during which he assaulted his mother and several court officers. The judge questioned the defendant's competency to stand trial but was reluctant to commit him for hospitalization.

The first psychiatric interview took place within an hour of the outburst. At that time, the defendant had little or no memory of the attack and was terrified about what had occurred. The psychiatrist formed the clinical impression that an epileptic seizure had occurred as a result of the defendant's withdrawal from barbiturates. For these reasons, he was given anti-epileptic medication. A second interview, conducted the next day, helped him understand what had occurred. He was then able to return to the arraignment proceedings and go forward with his trial.

Case 4. J.F., a 40-year-old black man, was charged with murder in the first degree. After his attorney and the prosecutor reviewed the evidence, it was agreed that the district attorney would accept a plea of guilty to a lesser charge, manslaughter. The defendant agreed that his attorney should adopt that strategy. At the time of his hearing, however, the defendant became acutely disorganized and suspicious as a result of hearing evidence about the brutality of the crime. At this point, he refused to go forward with the guilty plea. He insisted on a jury trial with a charge of first-degree murder, although there was strong evidence against him. The hearing was discontinued and the judge requested a conference with the court psychiatrist. He was concerned about the defendant's competency to stand trial and wondered whether he should be hospitalized. As an alternative to this, the court psychiatrist saw the defendant in two consultation sessions. By the end of the second session, the patient had apparently managed to alleviate enough of his guilt and anxiety that he was able to review realistically the merits of his attorney's original strategy and to recognize the self-destructive aspects of having pressed for a full jury trial.

CONCLUSIONS

We have described some of the appropriate uses of psychiatric expertise in pretrial evaluation and have emphasized that an outpatient service can both evaluate and treat defendants with psychiatric impairments that make them incompetent to stand trial. By so doing, psychiatrists support the patient-defendant's mental health and protect his legal right to a speedy trial.

Teaching Psychiatry in the Context of Dying and Death

BY DAVID BARTON, M.D.

Instruction in dying and death can be profitably included in the psychiatry curriculum. Through the use of this subject as a teaching focus, improved methods of psychosocial care are fostered and psychiatric principles and phenomena involving the patient and his interpersonal and sociocultural environment emerge in sharp relief. Also, students learn that the problems of dying and death are part of the problems of living.

IN RECENT YEARS, the psychosocial events related to life-threatening illness, dying, and death have received increased interest and attention. Advanced technical skills, the ability to prolong biological life, and the growing numbers of patients in terminal phases of illness who are treated in institutional settings have provided significant impetus in this direction. While in the past these areas have been dealt with largely in biological terms, increasing proximity to the dying patient and the need for more humanistic approaches to the care of these patients necessitate the development of skills to aid in the therapeutic management of the wide spectrum of psychosocial problems related to death and dying.

There is thus a growing need for instruction in this area for medical care-giving personnel. Instruction related to life-threatening illness, dying, and death can profitably be included in the medical school curriculum in personality development courses, general psychiatry courses, and clinical settings (1). An elective course for medical students, designed specifically to teach about the topic, has been developed at Vanderbilt University School of Medicine and is described in some detail in another article (2). In this course patient presentations, presentations by nonphysician health care personnel, and selections from the literature are used to provide focal points for extensive small group discussion. This format has proven to be a satisfactory method of highlighting a number of important and relevant issues, and it provides a setting in which students may begin to work through and synthesize their own attitudes toward and responses to death-related topics and begin to formulate their approaches to the management of the dying patient.

The topic should be recognized as one that is important to the teaching of psychiatry in medical education, for in the course of such instruction the student learns vital concepts related to the psychosocial aspects of medical and surgical practice and gains understanding about a number of basic psychiatric principles. While many of the principles and phenomena related to dying and the threat of death are common to other stages of development and life crises, in the context of life-threatening illness, dying, and death they achieve a level of visibility that facilitates their appreciation and reinforces learning.

Dr. Barton is Associate Professor of Psychiatry, Vanderbilt University School of Medicine, Nashville, Tenn. 37232.

RESPONSES OF THE INDIVIDUAL

Patients demonstrate clearly observable psychological phenomena in response to the crises of life-threatening illness and the events of dying. Basic phenomena such as symbolism are illustrated, and students can readily come to understand how a person might invest the events of illness and the accompanying body image changes, dying, and the threat of death with complex symbolic designations such as weakness, loss of control, or disintegration.

Individual psychodynamic patterns are brought into bold relief. For example, the person may perceive his illness as punishment for real or imagined guilt. There may be intense responses resulting from the person's shift from a position of independence to one of dependency. The person may sense a loss of control and enter into varying forms of behavior in an attempt to restore a sense of mastery. Ego defense mechanisms such as denial, reaction formation, intellectualization, and regression are clearly evident. As in other phases of development, individual adaptation or maladaptation takes varying forms depending on the person's life history and current circumstances. In recognizing this, students come to view dying as being as much a part of the life cycle as other stages, thereby expanding their understanding of human psychological development.

THE INTERPERSONAL DIMENSION

Dying and death are phenomena in which those persons relating to the patient are often dramatically affected by his illness and the patient's responses to it. In the family setting there frequently are marked shifts in attitudes and roles that illustrate a wide spectrum of family psychodynamics. Grief reactions and the process of mourning become apparent and are recognized as an inherent part of the human psychological response to loss.

It is possible that no other life circumstance provides as clear a setting for the student to recognize and begin to understand his own attitudes toward his patients and his expectations of his role as a physician. The bold and defi-

nite quality of the feelings evoked by a patient with life-threatening illness or by one who is dying facilitates the development of this awareness, and the student often experiences and is able to identify these feelings more distinctly than he can with other patients. The student may learn, for example, that his expectations of himself as a physician are set unrealistically high and that such attitudes may cause him to react to some patients with avoidance or overprotectiveness. Through his appreciation of these feelings, some of which may contribute to nontherapeutic responses to his patients, the student is helped to achieve a level of insight that allows him to incorporate self-awareness in the care-giving process. He thus learns that the attitudes and responses of care-giving personnel may serve to aid or impede a person's adaptation to his illness—a vital insight into the nature of the doctor-patient relationship.

Observation of the interaction within the care-giving milieu in response to dying and the threat of death provides the student with an appreciation of the sometimes subtle interchanges among personnel that occur in the provision of care for these patients. The importance of collaborative and cooperative efforts with other care-giving personnel such as nurses, clergymen, and pastoral counselors is emphasized, and the recognition that different persons bring varied expertise, skills, and attitudes into the care-giving process emphasizes the value of a multidisciplinary approach.

THE SOCIOCULTURAL DIMENSION

The wide variety of sociocultural issues related to dying and death may serve to direct the student's attention to the role of social institutions and cultural patterns in the provision of patient care. The student's frame of reference is substantially broadened as he learns that concepts from sociology, philosophy, anthropology, and theology may become significant in the provision of therapeutic care for the dying patient.

ETHICAL CONSIDERATIONS

Although ethics often becomes a salient issue in medical care, students are often excluded from the consideration of decisions involving ethical matters. Yet with increasing medical progress the ethical dilemmas involved in the care of a patient at times become primary considerations in that care. In the context of life-threatening illness, dying, and death, the student is provided with numerous situations that enable him to view the considerations of others and begin to formulate his own approach.

COMMENT

Life circumstances related to dying and death can provide an invaluable teaching setting and a set of situations in which students may learn basic psychiatric principles. Instruction in the topic can be profitably included in the psychiatry curriculum. Through the use of this subject as a teaching focus, improved methods of psychosocial care are fostered, and psychiatric principles and phenomena involving the person and his interpersonal and sociocultural environment emerge in sharp relief. Also, students learn that the problems of dying and death are part of the problems of living.

Ludwig von Bertalanffy
1901-1972

AS WE VALUE OURSELVES in our profession, so also we value those who have contributed to it. When their contributions are particularly important we signify this by electing them to Honorary Fellowship. On May 8, 1967, the American Psychiatric Association elected Ludwig von Bertalanffy an Honorary Fellow. Now, with a feeling of great loss, we must mark his death: on June 12, 1972, he died suddenly of a heart attack. A simple but beautiful memorial service was held in Williamsville, N.Y., where he lived while occupying the post of University Professor at the State University of New York at Buffalo. He would have thoroughly enjoyed being there, for besides the public figure there was also a very private Ludwig von Bertalanffy who delighted in closeness, intimacy, and friendship. He would have been pleased that there was much talk about his general systems theory and of new applications in the wind that offer hope for the solution of serious problems.

He is survived by his wife and co-worker of 47 years, Maria, a son and co-worker, Felix (a professor of anatomy at the University of Manitoba), his daughter-in-law, Giselle, a host of personal friends, and many others who have been inspired by and benefited from his works.

Ludwig and Maria von Bertalanffy had an almost ideal marriage. They met in a small bahnhof in the Tyrolean Alps, and from then on their life was one of great adventure—geographical, cultural, and, above all, intellectual. Within four years came the publication of *Modern Theories of Development*, which made him an international figure. But this only increased their sense of adventure. He remained always a man who could surmount difficulty, and there were many in his life, the most serious of which was his inability to gain an extension on his stay in this country as a Rockefeller Fellow, with the result that he had to return to Vienna in October 1938. Thus the Von Bertalanffys had to suffer through World War II in a country that had adopted an ideology completely inimical to everything they stood for.

His great conceptions of general systems theory, open systems theory, the *fliessgleichgewicht*—stodgily translated into English as "steady state" but more accurately as "a flowing or streaming equilibrium" (the primary spontaneous activity of the psychophysical organism)—and his concepts of humanism inspired many psychiatrists to alter their course in the pursuit of understanding the functions of the mind. A highlight was reached at the 1965, 1966, and 1967 annual meetings of the American Psychiatric Association, in which sessions on general systems theory and psychiatry were held. Von Bertalanffy's influence has continued to grow since his death, and at the present his works are required reading in an increasing number of psychiatric programs.

His major works included: *Kritische Theorie der Formbildung* (Berlin, 1928), translated into English as *Modern Theories of Development* (Oxford, 1933); *Theoretical Biology*, volumes I and II (Berlin, 1932, 1942); *Problems of Life* (New York, 1952); *Robots, Men and Minds* (New York, 1967); and *General Systems Theory* (New York, 1968).

Ludwig von Bertalanffy was one of the great changers of our time. With his fire and brilliance, his stubbornness and anger, his keen insight and his unwillingness to accept moral neutrality, he succeeded in revising our paradigms about the way the world and our minds work; he also succeeded in his great dream of bringing about unity through diversity. His 270 publications and 13 books, translated into eight languages, are the rich store he leaves for us.

WILLIAM GRAY, M.D.

LETTERS TO THE EDITOR

Drug Dosage in ECT

SIR: I would like to comment on and make some corrections in Dr. Corbett H. Thigpen's Letter to the Editor "Succinylcholine in EST" (June 1973 issue).

While the letter was primarily concerned with the use of pentylenetetrazol (Metrazol) in electroconvulsive therapy, the recommendation to use intravenous diazepam (Valium) as a quieting agent for postictal agitation bears repeating. This recommendation of Dr. Thigpen's provides a significant contribution, even as 20 years ago he and his colleagues made a significant contribution regarding the use of succinylcholine (1).

There are two corrections I must make. First, sodium methohexital (Brevital) should be used in a one-percent solution and dare not be used in a ten-percent solution, as was suggested by Dr. Thigpen. The amount of the dosage can range from 1.5 to 8 cc. Ten to 30 mg. of succinylcholine is sufficient to soften the convulsive reaction; more than this potentiates the hazards of postictal apnea, depending on subsequent experience with the patient. Second, the last sentence in the fourth paragraph should obviously read: "By using pentylenetetrazol [not succinylcholine] the seizure is little more pronounced than in an ordinary successfully administered electroshock treatment."

My thanks again to Dr. Thigpen.

MELVIN SIMONSON, M.D.
North Miami, Fla.

SIR: In response to Dr. Thigpen's Letter to the Editor I would like to present some added information on the technique of administering ECT.

In a letter to the *Journal of the American Medical Association* (1) I discussed the use of intravenously administered diazepam as a premedicating and amnesic agent for electoconvulsive treatment. It is my conviction that in replacing the traditional sodium methohexital with the intravenous diazepam the psychiatrist avoids much of the respiratory depression and postictal agitation associated with sodium methohexital and ECT.

However, the daily use of an antecubital vein leads to a palpable venous induration with tenderness within three or four days. One must then use another vein. In my use of diazepam, I never dilute it but perform a pseudo-flushing with succinylcholine as part of the premedication for ECT.

I have had several inquiries regarding my technique of using diazepam in place of sodium methohexital in ECT administration and would be glad to share it with anyone else who might be interested.

SIR: In his Letter to the Editor Dr. Thigpen describes an interesting way of enhancing incomplete seizures or avoiding missed seizures through the use of intravenous pentylenetetrazol. I wonder if he has considered the far simpler procedure of monitoring the patient's EEG during the procedure with the type of operating room monitor available in most hospitals.

This kind of monitoring has several advantages (1–3) over the use of pentylenetetrazol, namely: 1) it avoids adding another drug unnecessarily; 2) it permits total paralysis of the patient during treatment; 3) it provides adequate definition of the seizure and therefore allows for better planning of further treatment; and 4) most available monitors permit simultaneous or at least alternate recording of the EKG.

PAUL H. BLACHLY, M.D.
Portland, Ore.

SIR: Based on his observation that some patients who responded poorly to ECT had incomplete seizures, Dr. Thigpen recommends the following procedures to produce full seizures: administration of 1) 8 cc. of a ten-percent solution of sodium methohexital intravenously; 2) 20 to 80 mg. of succinylcholine, "depending on the size of the patient"; 3) 5 to 8 cc. of pentylenetetrazol intravenously; and 4) after a wait of one and a half minutes, ECT.

Although Dr. Thigpen obtained his desired results with this procedure, it is not to be recommended because it is, in the main, potentially hazardous.

A dose of 800 mg. of sodium methohexital is a very large dose to use for ECT. It definitely raises the convulsive threshold, giving rise to partial seizures. The usual dose of this drug for ECT varies from 50 to 100 mg. All barbiturates depress the function of the heart and are especially dangerous in poor-risk cardiac and respiratory patients.

Succinylcholine should never be administered "depending on the size of the patient." It should be administered with the thought in mind that the dose is related to the patient's pseudocholinesterase titer. Some patients may become fully relaxed with only 5 mg. of succinylcholine while others may be sufficiently relaxed with 80 mg. The pseudocholinesterase titer may be estimated indirectly by performing the tendon-reflex succinylcholine test (1). Succinylcholine weakens or paralyzes the muscles. As a consequence, the tendon reflexes are abolished. Abolition of the ankle jerk indicates that the patient is fully relaxed. Abolition of the knee jerk indicates that he is sufficiently relaxed for ECT. With this technique the usual dose of succinylcholine is from 5 to 30 mg. Using individualized doses of succinylcholine avoids the dangers of prolonged apnea from overdosage and fractures from underdosage.

Instead of reducing the convulsive threshold with pentylenetetrazol, it would be better to avoid the increase of threshold produced by high doses of sodium methohexital. This could be done by reducing the amount given or by eliminating it altogether and using the PM-GM method of anesthesia (2). This method involves giving the patient two successive stimuli with the ordinary shock machine at 100 volts for one-tenth or two-tenths of a second.

It has been known for a long time that the convulsive threshold varies over different parts of the brain. It is highest at the frontal poles and diminishes as the electrodes are moved backward over the posterior temple region. The convulsive threshold is lowest over the motor area. If this is kept in mind, changing the position of the electrodes to the posterior temporal area or over to the motor area may produce adequate convulsions. When convulsions cannot be obtained with one stimulus, giving two stimuli a few seconds apart with the voltage and time set high will invariably produce adequate convulsions. When adequate convulsions cannot be obtained with the double stimulation, one had better examine the patient neurologically to rule out brain disease causing an increase in the convulsive threshold.

I believe that the above suggestions are consistent with a more physiological and safer method of producing effective convulsive treatment.

DAVID J. IMPASTATO, M.D.
New York, N.Y.

Dr. Thigpen Replies

SIR: I am dismayed to learn that there was a serious error in the typescript of my letter that I failed to catch. It certainly might be fatal if a ten-percent solution of sodium methohexital were given intravenously. The sentence in the third paragraph should be corrected to read: "The average patient is given approximately 8 cc. of a one-percent solution of sodium methohexital (Brevital)." I think it is urgent that this correction be made. I am indeed thankful to Drs. Simonson and Impastato for calling this to my attention. I am also grateful for Dr. Simonson's kind remarks. As he suggested, in the last sentence of the fourth paragraph I find that succinylcholine is the word I intended rather than pentylenetetrazol.

I am interested in the observation of Dr. Wehlage that a localized phlebitis is often caused by intravenously administered diazepam. In my experience, the incidence of phlebitis has been decreased by using a different vein each day the drug is administered.

I have never given diazepam as a premedication or as an amnesic agent for ECT. I have, however, wondered if the use of diazepam might prevent the effective induction of the neural convulsion. In administering thousands of ECTs using sodium methohexital, I have seen only occasional and inconsequential respiratory depression. I would be quite interested in learning more of Dr. Wehlage's technique in using diazepam as a substitute for our usual anesthetic agent. I hope that he will give us additional information.

In my experience, there has been far less postictal agitation with the administration of sodium methohexital than with other anesthetic agents I have employed. In the days when no anesthetic at all was used, the postictal agitation impressed me as being very much more frequent and more extreme.

I appreciate Dr. Blachly's and Dr. Impastato's comments. From a practical standpoint, observation of the patient seems to be sufficient in determining whether or not a patient is having a full seizure. The use of the EEG would provide an interesting experimental study.

The comments of Dr. Impastato, as one of the world's leading investigators in this field, are of interest and should be given due consideration. It has not been my experience that multiple stimuli can be counted on to "invariably produce adequate convulsions."

Perhaps the chief point of my letter would have been more accurately indicated by a title such as "Pentylenetetrazol with ECT" rather than by the one under which it appeared. The comment on succinylcholine was really incidental. My associates and I have been deeply impressed with the importance of using pentylenetetrazol as an adjunct to electroconvulsive treatment in a fairly large percentage of patients. In our experience, when the seizure reaction is too brief or abortive the therapeutic effect has usually been insufficient to bring about the usual progress and anticipated recovery.

Approximately 12 years ago I had two patients with depression and one with mania who were admitted to the hospital after having received a number of seemingly adequate treatments elsewhere. Despite further treatment these patients still showed no improvement. I noted in each one that the seizure was incomplete; the manic patient was in very serious physical condition due to exhaustion. I decided to try supplementary pentylenetetrazol in this patient, and the result was dramatic. The two depressed patients also responded to the addition of pentylenetetrazol with much longer and more typical ictal reactions and with rapid therapeutic progress. Before this time I had thought of using supplementary pentylenetetrazol with patients whose reactions to ECT were insufficient or incomplete and whose progress was unsatisfactory, but I had hesitated because I thought it might counteract the anesthetic effect of the barbiturate. It was most gratifying to find that this was not so. On the basis of subsequent experience with several hundred patients who have received supplementary pentylenetetrazol with ECT, I am convinced that it can be a crucially important part of successful therapy.

The above letters indicate to me that a full report supported by statistical data would be of great value.

Augusta, Ga.

A Patient's View of Presenile Dementia

SIR: About two years ago I began to notice irregular memory lapses that lasted for only about a minute or two. As these lapses became more noticeable to me, my wife, and my children—not to mention my friends—I consulted the chief neurologist and the commanding officer of the local military hospital in my overseas post and asked their opinion on whether or not I might be subject to Pick's disease. This malady had caused my maternal grandfather's death at age 52 and possibly the subsequent death of my mother at age 47. No autopsy was made in her case, but the last time I saw her she could not recognize me. I have been told that a third generation of Pick's disease would be unusual.

I am aware that Pick's disease is rare and therefore on the back burner of medical research along with Alzheimer's disease. I am also aware that there is no effective medication to control the disease. (Please advise me if there is any effective medication.) My neurologist has prescribed levodopa (Larodopa) for me with no effect to date.

Optimistically, I have consulted two neurologists, a psychiatrist, a psychologist, and a local hospital, which administered EEG and brain scan tests that indicated "some irregularities." On the other hand, I find that my work is deteriorating; I find myself unable to make correct judgments under pressure.

In spite of my disease, I experience no pain and I usually exercise daily, including running a mile six days a week unless it rains. At the age of 45, I feel sound physically. On the other hand, I continue to have these minor, short-duration lapses of memory that, mercifully, cause me more embarrassment than anything else. At this point I feel somewhat like an absent-minded professor.

I have been able to acquire a listing of research on presenile dementia from the National Institute of Mental Health. This was reviewed by my neurologist. Based on his survey, there appears to be little or no effective research into this disease at present.

Since I continue to have regular memory losses, have exhausted my research into the subject, and am now eager to look for a new job and convince a prospective employer that it really does pay to hire the handicapped, I would wholeheartedly welcome news of any medications or procedures related to presenile dementia. I would volunteer to assist in such procedures within my ability to do so. I would be available to any physician interested in the causes and cures of this disease if it would be useful.

Early Childhood Illness and Choosing the Medical Profession

SIR: I was intrigued by the recent paper "Later Psychosocial Sequelae of Early Childhood Illness (Severe Croup)" (July 1973 issue), in which Dr. J.J. Sigal and associates examine certain hypotheses relating to the vulnerable child syndrome originally described by Green and Solnit (1). My response to this area of inquiry is both personal and professional and I wish to share both aspects.

At the age of nine years, I suffered a croup virus infection that required emergency tracheotomy treatment at a local hospital. Following the procedure, I was hospitalized on a pediatric ward for one and a half weeks and then recuperated at home for an additional two weeks. I was in the fourth grade of elementary school at the time and can recall aspects of my reentry into school after the traumatic event.

My memories of the acute infection, emergency medical evaluation, surgical procedure, events of hospitalization and postoperative care, and recuperative period remain painfully vivid. Prominent in my recollection are: my awareness of parental terror and my own fear of dying; my sense of being "attacked," with no way of escape, by well-intentioned physicians and nurses; my recurring experience of suffocation and pain associated with periodic tracheal suctioning; and my sense at the time of being abandoned and alone with no verbal means to communicate my distress. For years afterward, I had a recurring fear that the traumatic experience might happen again.

As I have made my way through medical training, psychiatric residency, and personal psychotherapy, I have reflected on the impact and influence of this experience on my behavior, on the goals and decisions I have made and continue to make, on the ways I typically respond to real or imagined danger situations, and on the vulnerabilities I am aware of. In a real way, this traumatic childhood event continues to affect my capacity to feel and express natural and appropriate aggressive impulses. How much of this handicap as well as others relates to my personal experience of this childhood disaster or to subsequent family processes influenced by it remains unclear to me.

I wish to indicate, however, that the experience has had some constructive dimensions. In subtle and complicated ways, it influenced my decision to pursue medical training and the formation of idealistic attitudes related to the practice of this profession. It contributed to a personal interest in working psychotherapeutically with persons who have serious life-threatening or life-afflicting illnesses. It has contributed to a professional interest in the hazards of physicianhood. In this latter regard, I have a personal commitment to appreciating the personal and family experiences that influence an individual's choice of medicine as a career and the kinds of vulnerabilities these experiences might continue to exert in the individual's practice of his or her profession. It would be intriguing to me if the experience of a life-threatening illness in childhood or the perception of such an illness in a significant family member ultimately proves to be one of the formative factors in the choice of medicine as a profession.

Internship for Psychiatrists

SIR: The material that follows constitutes a portion of my thoughts regarding the position presented by Dr. Engel in his Editorial "The Responsibilities of Psychiatry to Medicine" (June 1972 issue). I hope that the *Journal* does not allow this issue to fade into the past without first permitting full discussion of the matter. The questions raised in the article are too fundamental and timely to be dismissed with routine attention. I anticipate that this subject will continue to be with us for a long time.

The *Journal* serves as the best vehicle for its exposure. It is certainly better in many ways than the annual meeting of APA or any task force meeting. In fact, a special issue of the *Journal* devoted to reviewing the recommendation that emerged from the Residency Review Committee when the controversy arose over the internship might be in order. The question of the internship requirement itself is but one issue in the more central topic of the responsibilities and aims of the profession of psychiatry.

Dr. Engel's concerns are most valid, and welcome. I believe he has identified a major danger in today's psychiatry, namely, the increasing blurriness of the role of the psychiatrist. The

common features that once held the profession together seem to be undergoing gradual and progressive erosion. As the modern psychiatrist relaxes in his comfort and apathy, the nonmedical professionals in the field usurp duties and responsibilities that properly belong within psychiatry.

While the elimination of the internship requirement may not truly expedite the complete education of the psychiatrist, it does expedite the fragmentation of the profession. This has been brought on by psychiatrists themselves. Once the profession is weakened, the related mental health disciplines will quickly fill in the vacuum, to nobody's benefit.

It seems imperative that the Residency Review Committee that recommended the elimination of the internship, later adopted by the American Board of Psychiatry and Neurology, reconsider this decision. They must reexamine the contextual circumstances that made such a decision possible. When I learned of the recommendation I wondered whether the desire to feel "up with the times" had something to do with it. The need to be "modern" and "socially relevant" can conceivably influence this type of decision-making process.

I will not disguise my desire to see the internship reestablished as an essential cornerstone of psychiatric education. I would also like to see psychiatric educators independently establish the internship as a requirement for psychiatric residency. While their residency programs might suffer from a short-term effect of diminished applications, time will generously compensate for it.

In this same vein, psychiatry should aim at taking a more effective position in helping define the limits of responsibility and competence for paramedical professionals in the field of mental health. Psychiatry should come to see this as a major inherent responsibility, both for itself and for the public it serves. Experience would indicate that zealous paramedical professionals, forced by voluntary and involuntary circumstances, assume responsibilities for which their disciplinary training has not equipped them. The deleterious effect this has on the public, on these various professionals, and on psychiatry can be judged by the individual reader. Even though defining these limits is not a pleasant task, I see no alternative if we are to continue to show interest in safeguarding the public and in advancing our profession. Legislation, institutional regulation, and a more action-oriented desire to serve are necessary.

Psychiatry is, and should continue to be, a fundamentally biological science. Psychological mechanisms are but one expression of the organism at work. Even if many psychiatric therapeutic interventions, e.g., psychotherapy, do not appear biological on the surface, these interventions are based on a sound knowledge of biological functions. The seasoned psychiatrist seldom thinks of this; rather, it becomes a part of his personal and professional identity.

Psychiatry can continue to contribute to medicine as long as the psychiatrist continues to have a clear understanding of the disease process. No experience better allows for acquiring this knowledge than the rotating internship. Space limitations restrict me to just this consideration, even though there are many other gains to be made from the internship experience.

As a young psychiatrist I have had the opportunity to work closely with psychiatrists who have not experienced an internship. Various aspects of their professional dealings show the effects of their "expeditious" training. As they act as consultants to other physicians, as they evaluate "somatic" complaints, as they grope to understand other medical and surgical treatments, the deficits become visible. It is irresponsible to train psychiatrists in this fashion.

I can only hope that psychiatry can come to reason and reinstate the internship. Only then can we hope to reunite forces to carry on our basic medical responsibility. Only then will we be able to speak in terms of real progress.

Id-Ego: Synergy or Antagonism?

SIR: In response to Dr. Terry C. Rodgers' discussion of Drs. Hochman and Brill's article "Chronic Marijuana Use and Psychosocial Adaptation" (February 1973 issue), I would like to state that Freud's dictum "Where id was, there ego shall be" (1, p. 80), implying as it does the concept of innate id-ego antagonism and in consequence the "admirable" pursuit of ego mastery, is only a slightly altered version of Freud's earliest statement on id-ego relations. Here the ego (actually ego-superego) embodies such Victorian "virtues" as pride, noblemindedness, and, above all, the demands of objective reality expressed in the need to feel and act "properly." "Disgust, shame and morality" (2, p. 178) were in perpetual draconian conflict with "endogenous sexual excitations" or, later, libido, which was then translated as any sexual activity or fantasy other than "proper" sex—even though Freud stated, in apparent contradiction, that the "disposition to perversions of every kind is a general and fundamental mental human characteristic" (2, p. 191).

Many, if not most, present-day analysts (with the notable exception of ego psychologists) subscribe to Freud's formulation of id-ego synergy rather than antagonism: "There is no natural opposition between ego and id; they belong together, and under healthy conditions cannot in practice be distinguished from each other" (3, p. 201); "If the ego remains bound with the id and indistinguishable from it, then it displays its strength. The same is true of the relation between the ego and the superego" (4, p. 111). I highly recommend Apfelbaum's exposition of this issue (5).

The latter of Freud's formulations suggests the possibility that the absence of identifiable neurotic symptoms in the chronic marijuana smokers could be precisely because of the absence of any significant split between ego and id, a situation that Freud (at least at times) considered the hallmark of maturity and mental health, rather than, as Dr. Rodgers stated, "closer to the perversions."

Freud can perhaps be forgiven his ambivalence about completely committing himself to id-ego synergy, since this would have amounted to a total repudiation of his Victorian formative years. However, there are compelling reasons for believing that this was Freud's definitive formulation of structural relations in mental health. His last word, published posthumously, was that "the power of the id expresses the true purpose of the individual organism's life" (6, p. 148).

CHARLES F. HESSELBACH, M.D.
New York, N.Y.

Dr. Rodgers Replies

SIR: I basically agree with Dr. Hesselbach regarding the vicissitudes of Freud's metapsychology. Space obviously precludes any exposition of my understanding of the meaning and relationship of the terms ego and id beyond stating that they are abstractions having dynamic, economic, genetic, and adaptive distinctions as well as structural ones. Freud, however, repeatedly warned against taking abstractions (especially extrapolated ones) too literally (1, p. 97; 2, p. 79). By implication this brings us to the question of context.

I used the quote under discussion in commenting on the chronic marijuana user's narcissistic self-evaluation, tribal submersion into the "drug culture," and active pursuit of unfocused, drug-stimulated sensations and perceptions. The institutionalization of this "cult of experience" seems to me to express a psycho-epistemology (method of awareness) devoted to the mystical proposition that *unintegrated* subjective experience is a state to be actively desired and pursued. I compared the psychodynamics of this drug-induced assault on the integrative and conceptual faculties to that of the perversions because to me it is behavior that is pathologic in terms of action rather than symptoms and because it expresses a conflict between *ego* and *reality* in which reality is "rewritten" to conform to id desires by ego splitting and denial. The split, in my opinion, is within the ego and not between the ego and the id.

To my old and good friend, Dr. Hesselbach, I would like to add that I am of the view that any time two analysts discuss a theoretical point you end up with three opinions.

Communicative Meaning in Capgras Syndrome

SIR: In 1923 Capgras and Reboul-Lachaux (1) described the rare clinical condition about which Dr. Haslam commented in "A Case of Capgras Syndrome" (April 1973 issue). Although Dr. Haslam referred to some historical origins of the syndrome, no psychodynamic information is provided, nor is there a description of any psychotherapeutic attempt that might have been made. Rather, the reader is told that a good remission has been maintained with fluphenazine decanoate, although "a letter dated October 22, 1971, suggests that she [the patient] still held to her underlying delusional belief."

In 1972 (2) I described the successful treatment of a 12-year-old boy (possibly the youngest case of Capgras syndrome in the literature). My therapeutic approach was directed toward removing the misidentification by viewing it as a concrete communication of conflicting affects.

Most of the theories about the basis for Capgras syndrome fall into three spheres: 1) as a function of perception; 2) as a function of thought and concept formation; and 3) as a communication. The third theory is most useful psychotherapeutically: in the face of unacceptable sexual or hostile feelings, an ambivalently held object is split into good and bad objects. The symptom repair, as explained by Rado, allows the patient to express his anger. The anxiety generated by the conflict stimulates errors in perception. Concreteness in thinking and faulty generalizations provide the convincing logic.

My patient responded within nine months to anxiety reduction with oral thorazine administered intermittently in doses of 150 gm. a day. He also responded to repeated interpretation to explain the syndrome in terms of the changing and conflicting feelings he had for his parents—the accused doubles. His symptoms were seen in the context of disordered communication in the family, and his parents were also treated psychotherapeutically. Along with the relief of interpersonal family tensions the need for the syndrome disappeared. Now, five years later, my patient remains symptom free and has recently been admitted to a leading university.

BOOK REVIEWS

Differential Diagnosis in Clinical Psychiatry: The Lectures of Paul H. Hoch, M.D., *edited by Margaret O. Strahl, M.D., and Nolan D.C. Lewis, M.D. New York, Science House, 1972, 802 pp., $20.*

This remarkable volume contains Paul H. Hoch's lectures on clinical psychiatry that were delivered to psychiatrists training in psychoanalysis at the Columbia Psychoanalytical Clinic for Training and Research. Approximately 20 years have passed since then, years that were extremely productive in many areas of psychiatry in the sense that new methodologies were developed. However, clinical psychiatry and differential diagnosis in clinical psychiatry are being neglected more and more in many highly sophisticated research efforts. Therefore, a book by a great clinician is most welcome at this time. It has no parallel in recent psychiatric literature. The editors, Margaret O. Strahl and Nolan D.C. Lewis, have done a great service to psychiatry, and their effort to reconstruct the lectures from tape-recordings and notes has proven highly successful.

The book starts with an elaborate discussion of the history-taking interview technique. The differences in interviewing psychotic and neurotic patients are stressed. In the second part alterations of consciousness, conception, and perception are dealt with.

Part 3 contains an extensive discussion of organic reaction states. Just as the physical organism responds with an inflammation to many different noxious agents, so does the human mind respond to different etiological agents with the same symptomatology. Most interesting are the possibilities of an interchange between organic states and an underlying functional psychosis.

In his earlier years in America Hoch's special interest was alcohol-caused psychoses. In the chapter dealing with this subject, treatment is given more space than in other chapters outlining physiological or medical, sociological, and psychiatric approaches. Other organic psychoses dealt with extensively are senile and presenile psychoses and epileptic and convulsive states.

The introduction to the chapter on functional mental disorders points out that their essential features are identical in all cultures. The differential diagnosis of depression and manic psychosis versus schizophrenia is particularly important in view of the present studies on diagnostic differences in various countries.

Hoch's close acquaintance with psychoanalytical concepts is revealed in his extensive—and critical—discussion of psychodynamic theories of depression. Hoch called it "painful" to tell students that we do not know the origins of the great majority of mental disorders, but said that it is better to admit this and to go on from there than to imply that we know something that we do not.

In a profound discussion of the different groupings and concepts of schizophrenia Hoch warned against the many attempts to subordinate some of the known facts for the purpose of accommodating one or another idea about the disease. The chapter on clinical manifestations of schizophrenia is, in my opinion, the best outline of the psychopathology of schizophrenia that can be found anywhere. It includes the formulations of Kraepelin and Bleuler, adding to them psychoanalytical, gestalt, and other concepts. Among the descriptions of the subtypes, the part on the pseudoneurotic type of schizophrenia, created by Hoch and Polatin, is, of course, of particular interest and should lead to a wider acceptance and better understanding of this important contribution.

In the final chapter on etiology Hoch summarized his own theory that schizophrenia has an organic matrix and is a special form of integrative impairment. For further research he encouraged separate pursuits in the chemical, epidemiological, psychodynamic, and social fields and suggested a critical attitude toward all attempts at integration for some time to come.

LOTHAR B. KALINOWSKY, M.D.
New York, N.Y.

On Dying and Denying: A Psychiatric Study of Terminality, *by Avery D. Weisman, M.D. New York, Behavioral Publications, 1972, 237 pp., $9.95.*

Our society appears to be riding the crest of a wave of concern for the problems of dying persons. Perhaps this concern has been generated by a threat to our sense of immortality, which Robert Lipton ascribed to nuclear weapons. Perhaps it reflects the reassertion of humanistic values that we see occurring all around us and that, within the medical profession, we see taking the form of renewed interest in the dying person's human experience apart from his terminal disease. Perhaps, also, a growing concern within the profession has been provoked by the ethical dilemma—between preserving life and relieving suffering—that technological advances have thrust upon us.

In any event, the growth of this near-subspecialty in the past decade is truly remarkable. Professional societies have been established to further knowledge in this area and two journals, *Omega* and the *Journal of Thanatology*, are devoted exclusively to the subject. Indeed, the number of books and articles now devoted to thanatology exceeds the devotion and energy of even the specialist in this area.

A change in attitudes toward dying patients is long overdue. According to Seneca, we die not because we are sick, but because we are alive. This ancient bit of wisdom has gone unheeded by physicians, who have labored to sustain life as though death were conquerable and as though their dying patients were mere conglomerates of failing organs. The psychiatric contribution to the care of dying persons will come through an understanding of the psychological process of dying.

It is here that Dr. Weisman's book is an outstanding contribution. As its title implies, the author focuses upon a central aspect of this process—denying. The question most frequently raised by those who care for dying patients is what to tell them about their prognosis. Dr. Weisman, from his rich experience and study of dying persons over more than a decade, shows the irrelevance of this question. He tells us that the denial so universally encountered among these patients is not a static defense, as we are accustomed to thinking of it, but rather one aspect of an adaptive process by which dying persons gradually come to grips with their death.

Dr. Weisman describes opposing tendencies in dying patients. An inhibitory one, of which denial is a part, limits perception of the disturbing reality through avoidance and postponement. A facilitative one enhances perception and thought about this reality, thereby allowing drastic changes in identity and orientation toward life to take place. These tendencies oscillate over time and are influenced by the physical decline and progressive

change in interpersonal relationships experienced by dying persons.

Dr. Weisman eloquently illustrates his thesis with case reports, from which the humanity of his dying patients shines through. Despite his at times distracting habit of naming the various phases and stages, his concern for preserving the uniqueness of persons as they die remains abundantly clear. He stresses that those in caretaking professions should strive to preserve even the rudiments of responsible choice for their dying patients, which is, after all, the essence of their humanness.

In a number of chapters Dr. Weisman departs from the main theme of his book and explores certain emotional and social precipitants of death. He neglects the data that link bereavement to increased mortality, where a discussion of this subject might well begin. However, he makes it clear that a variety of emotional and social factors influence not only the quality of life but the timing of death for many dying patients.

Finally, Dr. Weisman tells us that acceptance of death is not only a possible but a desirable end to the process he describes. It is no achievement for those of us in good health. Rather, it is born of the weariness of terminal disease and a narrowing of attention to the current moment, from which vantage point the dying person may experience his being as timeless and his uniqueness as enduring.

RUSSELL NOYES, JR., M.D.
Iowa City, Iowa

Personality Differences and Biological Variations: A Study of Twins, *by Gordon Claridge, Sandra Canter, and W.I. Hume. Elmsford, N.Y., Pergamon Press, 1973, 168 pp., $11.40.*

In this compact monograph a group of enthusiastic investigators working at the University of Glasgow make good use of a sample of 95 pairs of twins to test out some of the senior author's psychophysiological hypotheses on the classification of personality. At the same time an effort is made to estimate the contribution of heredity to variations among people in each of the tests, measurements, or statistically derived personality factors under consideration.

The classic twin method—comparison of monozygotic and dizygotic twins, with its value and limitations—is well described in an introductory section and then applied in successive chapters to personality traits, cognitive function, physiological measures, and tolerance to sedative drugs.

There are some interesting findings. Sandra Canter points out, for example, that a personality trait, such as sociability, may have important genetic determinants but that these can be masked, as long as the twins live together, because of mutual interaction and the assumption of complementary roles; the twins become more alike after they are separated. In another area, tests of cognitive function seem to indicate that general intelligence is most influenced by heredity and that creative thinking is correlated with intelligence (and hence genetically influenced) only up to a certain IQ level. In this area, however, the age and separation of the twins seem to increase the differences between them.

Physiological measures and sedation threshold are analyzed individually, and the data are then subjected to factor analysis. Two principal factors are isolated—one involves activation (sedation threshold and heart-rate level) and is termed "tonic arousal," and the second is concerned with regulation (EEG alpha activity) and is termed "arousal modulation." It is the latter that seems to be more influenced by heredity. Both of them form the parameters of Claridge's descriptive model of personality, with two major dimensions—neuroticism and "psychoticism."

The mere clinician may question the usefulness of such elaborate methods of describing personality, but typology has a long history in psychiatry, and efforts to define dimensions and measure them deserve his attention. For dessert, he may enjoy the brief vignettes, in chapter 7, of the four monozygotic twin pairs with high degrees of discordance, particularly on tests of creativity, and speculate on the design of prospective studies to learn how such divergent spirals grow.

This book reports an elaborate, tightly argued, and clearly presented study that not only will be of interest to the specialist but ought to refine clinical observation and stimulate ideas among psychopathologists of all disciplines.

JOHN D. RAINER, M.D.
New York, N.Y.

The Victim Is Always the Same, *by I.S. Cooper, M.D. New York, Harper & Row, 1973, 160 pp., $6.95.*

Dr. Irving S. Cooper is world-renowned for his revolutionary discoveries of neurosurgical approaches to the treatment of Parkinson's disease and other extrapyramidal disorders as well as for his pioneering work in the field of cryogenic surgery. His interests for years have transcended his profession, and he has written many high-quality articles relating to the various fields of literature, history, and medicine. In this brief monograph he plunges boldly into medical-ethical issues and problems that confront not only physicians but also patients and their families.

When his latent yet mostly blatant criticisms of certain psychiatric practices and attitudes are encountered for the first time, any psychiatrist is apt to feel like a young person just soundly spanked. In the final analysis, however, the reader will find himself thoroughly educated about the condition of dystonia musculorum deformans, and it is to be hoped that if he ever encounters the disorder in his practice, he will not miss the diagnosis.

In a humanistic, autobiographical style Dr. Cooper takes the reader step by step through the process of encounter, diagnosis, management, and final, almost total, symptomatic relief of two young persons who were afflicted with this rare form of dystonia. The text is highly emotional in tone, and the reader cannot help but be moved by a variety of feelings as the story unfolds.

There is little question that Dr. Cooper tries very hard to hide his justifiable, righteous indignation toward what he deemed psychiatric mismanagement of his young patients. He specifically states that he does not purport to indict or criticize psychiatry in general. However, in these days of increasing need for peer review and self-assessment, Dr. Cooper need not have been so apologetic. The whole issue was simply that some psychiatrists missed the diagnosis and, undoubtedly in good faith but with some ignorance, tried to treat these children with psychotherapy, multiple drugs, and unnecessary hospitalizations, the latter resulting in much expense to the patients' families in terms of time, money, and emotional trauma. Dr. Cooper is faulting only these psychiatrists' myopic diagnostic approach and resultant mistakes in clinical judgment as he laments the consequent dehumanization of the patients and their families.

Although the author did not intend to write his book primarily for the medical reader, it is a book to be highly recommended for all psychiatrists, internists, neurologists, neurosur-

geons, pediatricians, and family physicians. The author's point is well taken, and psychiatrists in particular have much to learn from it.

The book can be read quickly; it is stylistically well written. One example of the author's sincerity and warmth appears in the preface:

> I should have wished to write a poem had I been able, for perhaps in poetry one could compress the strength, maturity, courage, loneliness, torment, despair, effort, faith, humanity, of these children. In their condition is the distillate of human authenticity. In spite of the condition inflicted upon them, they remain loyal to life and to themselves.

Dr. Cooper raises one other important moral-ethical issue, namely, who has the right to decide which person is to be operated upon and which is not when the newly developed and previously untried surgical procedures carry not only possibilities of relief from suffering but unknown risks as well?

Another reward gained from reading this book is the feeling that one has just rendezvoused with genius.

WILLIAM W. ZELLER, M.D.
Hartford, Conn.

Manuel de Psychiatrie de l'Enfant, *by J. de Ajuriaguerra. Paris, Masson & Cie, 1970, 1023 pp., 180 F.*

This imposing volume, by a distinguished Spanish-born neurologist and psychiatrist, is the result of the author's effort to present the material from his courses offered to medical students in a comprehensive handbook. In view of the vastness of this endeavor, only some highlights and the author's general orientation can be discussed here.

In the introductory chapter, child psychiatry, through the confluence of various disciplines, is defined as "a genetic psychopathology which deals with development and its deviations and which, knowing the genesis of functions and their evolution in time, focuses on the importance of the possibilities of the child at each level of his evolution and aims at understanding the various phases of this chronology in the light of the relationship between the organism and the environment." Although the polarization of organogenesis and psychogenesis cannot be easily overcome, the author shows how the succeeding maturational levels and functional realizations of the child take place along a developmental schema that unfolds itself in space and in time and in which "there is room for the lived and for the imaginary, without the lived taking a mythical meaning and the imaginary a disembodied meaning."
